Report Definitions

TNC	Too Numerous To Count
DET	Analyte DETECTED
ND	Analyte NOT DETECTED at or above the minimum reporting limit
NR	Not Reported
RPD	Relative Percent Difference
ICV	Initial Calibration Verfiication
CCV	Continuing Calibration Verification Standard
SSV	Secondary Source Verfication Standard
LCS	Lab Control Spike - Lab matrix prepared with known concentration of analyte/s of interest analyzed by method.
MS	Matrix Spike - Sample prepared with known concentration of analyte/s of interest analyzed by method.
MSD	Matrix Spike Duplicate - Duplicate sample prepared with known concentration of anlayte/s of interest analyzed by method.
MRL	Minimum Reporting Limit
%REC	Percentage Recovery of known concentration added to matrix
Batch	Group of samples prepared for analysis not to exceed 20 samples.
Matrix	Material containing analyte/s of interest
Surrogate	Analyte added to sample to determine extraction efficiency of method.

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Hattiesburg, MS 39404-5369

RE: Mobile Quarterly Wells New Permit

Enclosed is the revised report for samples received by the laboratory on 09/22/2022 08:06. This report supercedes any previous version of the above noted work order. If you have any questions concerning this report, please feel free to contact the office.

Sincerely,

Mitch Spicer

Lab Director
Micro-Methods Laboratory, Inc.

DISCLAIMER

The results only relate to the items or the sample and/or samples received by the laboratory. This report shall not be reproduced except in full, without the approval of the laboratory. All NELAP certified test methods performed meet the requirements of NELAC 2009 Standards. Any variances and/or deviations specific to this analytical report are referenced in the lab report using qualifiers and detailed explanations found in the case narrative.

CASE NARRATIVE SUMMARY

All reported results are within Micro-Methods Laboratory, Inc.defined laboratory quality control objectives unless detailed in narrative summary or identified as qualifications. NOTE: All results listed on this report are calculated on a wet weight basis (as received by the laboratory) unless otherwise noted in the analysis qualification sections.

Summary Comments:

REVISED REPORT-SCH 12/20/2022:
Results for EPA 8270 reported to the MDL. Results between the MDL and MRL flagged as a "J" value. False positives abvoe the MDL but below the MRL removed from reporting. Revised report issued. 8270D

Volatile Technician Comments - BSF:
Sample(s) analyzed with zero headspace. 8260D-5030B
pH of sample(s) is less than two in preserved vials. 8260D-5030B

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Chloride-ASTM D 512-12

Qualifiers:

L1 LCS and/or LCSD Recovery Limit exceeded.

Chloride
2I30012-BSD1

Semi-Volatile Compounds-EPA 8270D

Qualifiers:

CC-01 CCV exceeds acceptance limits. Sample results reported from this calibration were below the reporting limits.

2-Methylnaphthalene, 3 & 4-Methylphenol, Fluoranthene
2209354-01[Mobile/RC-2], 2I28027-DUP1, 2209354-05[Mobile/T-2], 2I28027-BLK1, 2209354-04[Mobile/T-1]

CC-03 CCV exceeds acceptance limits. QC Results reported from this calibration within acceptance limits.

2-Methylnaphthalene, Fluoranthene
2I28027-BS1, 2I28027-BSD1, 2I28027-MS1

J Detected above the MDL but below the MRL; therefore, result is an estimated concentration (CLP J-Flag).

2,4-Dimethylphenol, 2-Methylphenol, 3 & 4-Methylphenol, Acenaphthylene, Anthracene, Benzo (a) pyrene, Benzo (b) fluoranthene, Benzo (k) fluoranthene, Carbazole, Dibenz (a,h) anthracene, Fluoranthene, Pyrene
2209354-05[Mobile/T-2], 2209354-03[Mobile/RC-3], 2209354-01[Mobile/RC-2], 2209354-04[Mobile/T-1], 2209354-02[Mobile/ RW-3A], 2209354-06[Mobile/E-1]

L1 LCS and/or LCSD Recovery Limit exceeded.

Bis(2-ethylhexyl)phthalate, Pentachlorophenol
2I27021-BSD1, 2I27021-BS1

L3 LCS/LCSD Precision Limit exceeded.

2-Methylphenol
2I28027-BSD1

M5 Spike amounts should be in the range of 1 to 5 times the background level when a sample contains the target parameter in order to effectively evaluate spike recoveries. Batch acceptance is based on LCS/LCSD recoveries.

1-Methylnaphthalene, 2,4-Dimethylphenol, 2,4-Dinitrophenol, 2-Methylnaphthalene, Acenaphthene, Anthracene, Carbazole, Dibenzofuran, Naphthalene, Phenanthrene, Pyrene
2I27021-MS1

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Semi-Volatile Compounds-EPA 8270D

Qualifiers:

SR01 The surrogate recovery for this sample is not available either due to matrix interference or due to sample dilution required for high analyte concentration/matrix interferences.

2-Fluorophenol

2209354-03[Mobile/RC-3]

SR05 Acid surrogate recovery outside of control limits. The data was accepted based on valid recovery of remaining two acid surrogates.

2-Fluorophenol

2209354-01[Mobile/RC-2]

SR06 Base/Neutral surrogate recovery outside of control limits. The data was accepted based on valid recovery of remaining two base/neutral surrogates.

Nitrobenzene-d5

2I27021-DUP1

SR08 Surrogate recovery outside of control limits. The data was accepted based on valid recovery of the remaining surrogates.

2-Fluorophenol, Phenol-d5

2209354-04[Mobile/T-1], 2209354-03[Mobile/RC-3]

Nitrate Nitrogen Hach-HACH 10206

Qualifiers:

HT-03 This sample was analyzed outside the recommended holding time.

Nitrate as N

2209354-05[Mobile/T-2], 2209354-06[Mobile/E-1]

HT-06 The original analysis of this sample yielded QC recoveries outside acceptance criteria. It was re-analyzed after the recommended maximum hold time for confirmation of reported results.

Nitrate as N

2209354-01[Mobile/RC-2], 2209354-02[Mobile/RW-3A], 2209354-03[Mobile/RC-3], 2209354-04[Mobile/T-1]

RE: Mobile Quarterly Wells New Permit

Enclosed is the revised report for samples received by the laboratory on 09/21/2021 16:02. This report supercedes any previous version of the above noted work order. If you have any questions concerning this report, please feel free to contact the office.

Sincerely,

Mitch Spicer

Lab Director
Micro-Methods Laboratory, Inc.

DISCLAIMER

The results only relate to the items or the sample and/or samples received by the laboratory. This report shall not be reproduced except in full, without the approval of the laboratory. All NELAP certified test methods performed meet the requirements of NELAC 2009 Standards. Any variances and/or deviations specific to this analytical report are referenced in the lab report using qualifiers and detailed explanations found in the case narrative.

CASE NARRATIVE SUMMARY

All reported results are within Micro-Methods Laboratory, Inc.defined laboratory quality control objectives unless detailed in narrative summary or identified as qualifications. NOTE: All results listed on this report are calculated on a wet weight basis (as received by the laboratory) unless otherwise noted in the analysis qualification sections.

Summary Comments:

Volatile Technician Comments - BSF:
Sample(s) analyzed with zero headspace. 8260D-5030B
pH of sample(s) is less than two in preserved vials. 8260D-5030B

Report resubmitted with revised format at client's request - HMS 12/22/2021

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

SIM PAH Analysis by GC/MS-EPA 8270D

Qualifiers:

B-06 Possible laboratory contamination.

Naphthalene
1I28028-BLK1

CC-01 CCV exceeds acceptance limits. Sample results reported from this calibration were below the reporting limits.

2,4-Dinitrophenol
1I27031-BLK1, 1I27031-DUP1, 2109390-01[Mobile/RW-1], 2109390-02[Mobile/RW-2]

CC-02 ICV exceeds the acceptance limit. Sample results reported from calibration were below the reporting limits.

Di-n-octyl phthalate
1I27038-BLK1, 2109390-03[Mobile/RC-1], 2109390-04[Mobile/RC-1A]

CC-03 CCV exceeds acceptance limits. QC Results reported from this calibration within acceptance limits.

2,4-Dinitrophenol
1I27031-BS1, 1I27031-BSD1

CC-06 ICV exceeds the acceptance limit. QC results reported from calibration were within acceptance limits.

Di-n-octyl phthalate
1I27038-BS1, 1I27038-BSD1

J Detected above the MDL but below the MRL; therefore, result is an estimated concentration (CLP J-Flag).

2,4-Dimethylphenol, 2,4-Dinitrophenol, 2-Methylphenol, 4-Chloro-3-methylphenol, Acenaphthylene, Anthracene, Benzo (a) pyrene, Benzo (b) fluoranthene, Benzo (k) fluoranthene, Chrysene, Dibenz (a,h) anthracene, Indeno (1,2,3-cd) pyrene
2109390-04[Mobile/RC-1A], 2109390-03[Mobile/RC-1], 2109390-01[Mobile/RW-1], 2109390-02[Mobile/RW-2]

L3 LCS/LCSD Precision Limit exceeded.

Fluoranthene
1I27038-BSD1

P3 Sample/Sample Duplicate RPD exceeded acceptance criteria.

Anthracene, Benzo (a) pyrene, Benzo (k) fluoranthene, Fluoranthene, Indeno (1,2,3-cd) pyrene, Naphthalene
1I28028-DUP1, 1I27038-DUP1

SR01 The surrogate recovery for this sample is not available either due to matrix interference or due to sample dilution required for high analyte concentration/matrix interferences.

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

SIM PAH Analysis by GC/MS-EPA 8270D

Qualifiers:

2-Fluorobiphenyl, Nitrobenzene-d5

1I28028-DUP1, 2109390-02[Mobile/RW-2]

SR06 Base/Neutral surrogate recovery outside of control limits. The data was accepted based on valid recovery of remaining two base/neutral surrogates.

Nitrobenzene-d5

2109390-01[Mobile/RW-1]

pH-SM 4500-H+B-2011

Qualifiers:

HT-02 At the time of receipt, this sample had already exceeded the recommended holding time.

Analyte & Samples(s) Qualified:

2109390-01[Mobile/RW-1], 2109390-02[Mobile/RW-2], 2109390-03[Mobile/RC-1], 2109390-04[Mobile/RC-1A]

RE: Mobile Quarterly Wells New Permit

Enclosed is the revised report for samples received by the laboratory on 09/23/2021 08:35. This report supercedes any previous version of the above noted work order. If you have any questions concerning this report, please feel free to contact the office.

Sincerely,

Mitch Spicer

Lab Director
Micro-Methods Laboratory, Inc.

CASE NARRATIVE SUMMARY

All reported results are within Micro-Methods Laboratory, Inc.defined laboratory quality control objectives unless detailed in narrative summary or identified as qualifications. NOTE: All results listed on this report are calculated on a wet weight basis (as received by the laboratory) unless otherwise noted in the analysis qualification sections.

Summary Comments:

Volatile Technician Comments - BSF:
Sample(s) analyzed with zero headspace. 8260D-5030B
pH of sample(s) is less than two in preserved vials. 8260D-5030B

Report resubmitted with revised format at client's request - HMS 12/22/2021

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

SIM PAH Analysis by GC/MS-EPA 8270D

Qualifiers:

B-06 Possible laboratory contamination.

Naphthalene

1I28028-BLK1

CC-01 CCV exceeds acceptance limits. Sample results reported from this calibration were below the reporting limits.

2,4-Dinitrophenol

1I27031-BLK1, 1I27031-DUP1

CC-02 ICV exceeds the acceptance limit. Sample results reported from calibration were below the reporting limits.

Di-n-octyl phthalate

1I27038-BLK1, 2109427-03[Mobile/RC-2A]

CC-03 CCV exceeds acceptance limits. QC Results reported from this calibration within acceptance limits.

2,4-Dinitrophenol

1I27031-BS1, 1I27031-BSD1

CC-06 ICV exceeds the acceptance limit. QC results reported from calibration were within acceptance limits.

Di-n-octyl phthalate

1I27038-BS1, 1I27038-BSD1

J Detected above the MDL but below the MRL; therefore, result is an estimated concentration (CLP J-Flag).

2,4-Dimethylphenol, 4-Chloro-3-methylphenol, Acenaphthene, Bis(2-ethylhexyl)phthalate, Carbazole, Fluoranthene, Fluorene, Pyrene

2109427-04[Mobile/RC-3A], 2109427-07[Mobile/RC-3], 2109427-01[Mobile/RW-4], 2109427-02[Mobile/RW-5]

L3 LCS/LCSD Precision Limit exceeded.

Fluoranthene

1I27038-BSD1

P3 Sample/Sample Duplicate RPD exceeded acceptance criteria.

Anthracene, Benzo (a) pyrene, Benzo (k) fluoranthene, Fluoranthene, Indeno (1,2,3-cd) pyrene, Naphthalene

1I28028-DUP1, 1I27038-DUP1

SR01 The surrogate recovery for this sample is not available either due to matrix interference or due to sample dilution required for high analyte concentration/matrix interferences.

2-Fluorobiphenyl, Nitrobenzene-d5

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

RE: Mobile Quarterly Wells New Permit

Enclosed is the revised report for samples received by the laboratory on 09/24/2021 08:20. This report supercedes any previous version of the above noted work order. If you have any questions concerning this report, please feel free to contact the office.

Sincerely,

Mitch Spicer

Lab Director
Micro-Methods Laboratory, Inc.

CASE NARRATIVE SUMMARY

All reported results are within Micro-Methods Laboratory, Inc.defined laboratory quality control objectives unless detailed in narrative summary or identified as qualifications. NOTE: All results listed on this report are calculated on a wet weight basis (as received by the laboratory) unless otherwise noted in the analysis qualification sections.

Summary Comments:

Volatile Technician Comments - BSF:
Sample(s) analyzed with zero headspace. 8260D-5030B
pH of sample(s) is less than two in preserved vials. 8260D-5030B

Report resubmitted with revised format at client's request - HMS 12/22/2021

SIM PAH Analysis by GC/MS-EPA 8270D

Qualifiers:

B-06 Possible laboratory contamination.

Naphthalene
1I28028-BLK1

CC-01 CCV exceeds acceptance limits. Sample results reported from this calibration were below the reporting limits.

2,4-Dinitrophenol
1I27031-BLK1, 1I27031-DUP1

CC-02 ICV exceeds the acceptance limit. Sample results reported from calibration were below the reporting limits.

Di-n-octyl phthalate
1I27038-BLK1

CC-03 CCV exceeds acceptance limits. QC Results reported from this calibration within acceptance limits.

2,4-Dinitrophenol
1I27031-BS1, 1I27031-BSD1

CC-06 ICV exceeds the acceptance limit. QC results reported from calibration were within acceptance limits.

Di-n-octyl phthalate
1I27038-BS1, 1I27038-BSD1

J Detected above the MDL but below the MRL; therefore, result is an estimated concentration (CLP J-Flag).

2,4-Dimethylphenol, 4-Chloro-3-methylphenol, Acenaphthylene, Benzo (a) anthracene, Benzo (a) pyrene, Benzo (b) fluoranthene, Benzo (k) fluoranthene, Bis(2-ethylhexyl)phthalate, Carbazole, Chrysene, Dibenz (a,h) anthracene, Fluoranthene, Fluorene, Indeno (1,2,3-cd) pyrene, Pyrene
2109469-04[Mobile/T-2], 2109469-03[Mobile/T-1], 2109469-01[Mobile/E-1], 2109469-02[Mobile/UG-2]

L3 LCS/LCSD Precision Limit exceeded.

Fluoranthene
1I27038-BSD1

P3 Sample/Sample Duplicate RPD exceeded acceptance criteria.

Anthracene, Benzo (a) pyrene, Benzo (k) fluoranthene, Fluoranthene, Indeno (1,2,3-cd) pyrene, Naphthalene
1I28028-DUP1, 1I27038-DUP1

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Mr. George Brown
Cavenham Forest Industries
Treated Wood Products
P. O. Box 2219
Gulfport, MI 39503

Dear George:

Re: 159-163: Mobile Groundwater Appendix IX Constituents

Samples of groundwater received here March 27 have been analyzed for organic priority pollutants, metals, cyanide, and sulfide. Additional parameters required for the Appendix IX analyses were sent to another laboratory and we will forward those results to you as soon as they are available. Results are shown in Tables 1 through 5 based upon the samples as received. Chain-of-custody information is shown in Appendix A.

No unusual components were detected besides those expected from creosote/pentachlorophenol contamination. The upgradient well (UG-2) contained elevated levels of phenolic components (2,4-Dimethyl Phenol) relative to the polynuclear aromatics (naphthalene,etc.) expected from creosote contamination. Also the ratio of polynuclear aromatics observed in UG-2 did not match those normally observed from creosote contamination.

Please call if we can be of further assistance.

Very truly yours,

Dave Edelman, Jr.

DAVE EDELMAN, JR., Ph.D.
Environmental Laboratory
Coordinator

JAMES RIVER CORPORATION
CORPORATE ENVIRONMENTAL SERVICES-WEST
904 N.W. Drake Street, Camas, WA 98607-1999 (206) 834-4444

June 1, 1987

Mr. George Brown
Cavenham Forest Industries
Treated Wood Products
P. O. Box 2219
Gulfport, MI 39503

Dear George:

Re: 159-163: Mobile Groundwater Appendix IX Constituents

Samples of groundwater received here March 27 have been analyzed for Appendix IX constituents. These are the additional parameters required for the Appendix IX analyses which were sent to another laboratory (5/14/87 letter from DLE to GB). Results are shown in Tables 1 through 5 based upon the samples as received.

No unusual components were detected besides those expected from creosote/pentachlorophenol contamination.

Please call if we can be of further assistance.

Very truly yours,

Dave Edelman, Jr.

ESD PROJECT NO. 86-003

INTRODUCTION

Bruce Ferguson and Don Hunter, US-EPA, Region IV, Environmental Services Division (ESD), Hazardous Waste Section (HWS), conducted a comprehensive ground water monitoring evaluation (CME) at the Crown Zellerbach Corporation, Southern Timber and Wood Products Division facility, Mobile, Alabama (Figure 1) during October 9 and 10, 1985. This evaluation was conducted at the request of the US-EPA, Region IV, Residuals Management Branch. J. Michael Foreman, Environmental Coordinator, Crown Zellerbach and David Killingsworth, Alabama Department of Environmental Management (ADEM) assisted with sampling during the evaluation and received split samples for some analyses. Eddie Wolfe and Brad Gane, ADEM, also visited the site during the investigation.

The purpose of the evaluation was to determine if the facility was in compliance with ground water monitoring regulations and standards of 40 CFR Part 265, Subpart F.

BACKGROUND

The Crown Zellerbach Corporation operated a facility for the preservative treatment of wood products located in Mobile, Alabama. The facility has been inactive for the past two to three years and Crown Zellerbach would like to attain closure of it under RCRA guidelines and regulations. The RCRA regulated hazardous waste management area consisted of an aeration pond and two concrete lined vacuum ponds (Figure 2). Ground water downgradient from the ponds has been determined to contain hazardous compounds relating to the operations of this facility. Crown Zellerbach has installed approximately thirty wells for the purpose of determining the rate and extent of migration and the concentrations of these hazardous waste constituents in the ground water.

The facility is in assessment and in September 1985 installed six additional wells for assessment purposes. Since the facility has been closed for several years, complete files and records were not available for on site inspection. Preliminary geotechnic site work shows the underlying strata consists of organic clay fill, silty sand, silty clay, lower sand and marine clay.

SUMMARY

The facility upgradient wells are properly located and do not indicate any effects from the former wood preserving operations. Ground water downgradient from the RCRA regulated aeration pond and vacuum ponds has been grossly affected by leakage from these units.

From discussion with Mr. Foreman it was determined that the facility is meeting the intent and requirements of 40 CFR Part 265, Subpart F. The facility's final Ground Water Quality Assessment Plan was due to be submitted to EPA Atlanta by October 31, 1985.

SAMPLING

Ground water samples were collected from two upgradient wells (UG 1&2) and six downgradient wells (B-3, B-15, B-2, B-6, B-4A, and B-9). These eight wells are the RCRA compliance monitoring wells which the facility designated for the RCRA regulated waste units. The location of these wells satisfies the requirements of a Notice of Violation issued by the Alabama Department of Environmental Management dated July 24, 1985. The first three downgradient wells were downgradient from the aeration pond, the second three were downgradient from the vacuum ponds. All wells were PVC cased to total depths between 21-37 feet. Well B-4A had a 10-foot screen and all others had 5-foot screens. Three well volumes were bailed from the two upgradient and four of the downgradient wells prior to collecting the samples. Downgradient wells B-15 and B-9 were heavily contaminated with a "heavier than water" oily liquid. There was only a small volume of water in these wells and after several bailers were pulled, only the oily liquid was present. Samples from these two wells were collected with the facility's dedicated PVC bailers. Conductivity and pH determinations were not made on these wells. Recovery of well B-15 was slow and samples had to be collected during two different days. A summary of the analytical data from all samples collected is given in Table 1. The raw data are included in the appendix.

With the exception mentioned above, all samples were collected and handled in accordance with the Water Surveillance Branch Standard Operating Procedures/ Quality Assurance Manual (Draft 1980). All samples were analyzed in accordance with the Analytical Support Branch Operations and Quality Control Manual, June 1985. STORET station locations and field data have been submitted for entry into the STORET system.

RESULTS

A review of the metals data showed the presence of eight metals in upgradient well 1. Concentrations of these metals ranged from 50 ug/l barium to 716 mg/l sodium. Eleven metals were detected in upgradient well 2 with concentrations ranging from 13 ug/l zinc to 56 mg/l sodium. From eight to eleven metals were detected in the downgradient wells sampled. Concentrations of these ranged from 13 ug/l chromium and zinc to 1,200 mg/l sodium. Barium and chromium were the only metals of the National Interim Primary Drinking Water Standards (NIPDWS) detected in the well samples and neither exceeded the maximum allowable level.

Phenols (4AAP) were detected in upgradient well 1 at an estimated concentration of 28 ug/l and upgradient well 2 at a concentration of 38 ug/l. The downgradient wells contained phenols at concentrations ranging from 260 ug/l in well B-4A to 44,000 ug/l in well B-15.

Presumptive evidence of caprolactam at an estimated concentration of 70 ug/l in upgradient well 1 was the only organic compound detected in either of the two upgradient wells.

Twenty-seven different organic compounds were identified and quantified in the samples collected from the six downgradient wells. The majority of these 27 compounds were polynuclear aromatic hydrocarbons (PAH) associated with the creosote process of wood preserving. Well B-15, downgradient from the aeration

pond, contained the greatest number and highest concentrations of these organic compounds. Concentrations ranged from 2,700 ug/l acenaphthylene to 380,00 ug/l naphthalene. Well B-4A, downgradient from the vacuum ponds, contained the least number and lowest concentrations of the PAH. Downgradient well B-9 was not sampled for extractable organic analyses. Several phenolic compounds and organic solvents were also identified and quantified in the downgradient well samples. Presumptive evidence, at estimated concentrations from .7 to 100,000 ug/l, for an additional 19-35 organic compounds was reported in the six downgradient well samples (Table 1).

Conductivity and pH measurements made during this investigation are shown in the following table.

Well	Station ID	pH (SU)	Conductivity (umhos/cm)
UG-1	CZ-1	4.6	380
UG-2	CZ-2	6.0	600

Dear Mr. Russell

Enclosed you will find a copy of the analysis of the water samples that were taken from the wells located at the Cavenham's Mobile facility in September of 1988.

If you have any questions, please contact me at (205) 271-7489.

CAVENHAM FOREST INDUSTRIES, INCORPORATED
Comprehensive Groundwater Inspection

November 14, 1988

Alabama Department of Environmental Management
Field Operations Division
Fiscal Year 1988

INTRODUCTION

On September 20-21, 1988, staff members of the Field Operations Division of the Alabama Department of Environmental Management (ADEM) conducted a comprehensive groundwater inspection at the Cavenham Forest Industries, Incorporated facility at Mobile, Alabama in Mobile county (see Figure 1). The persons involved with the sampling during the investigation were as follows:

Brien Diggs	ADEM/FOD
Ronald Ford	ADEM/FOD
Jim Thomas	ADEM/WD
George Weiss	Cavenham Forest
Winston Russell	Woodward-Clyde Consultants

Mr. Jim Thomas was the Departmental geologist from the ADEM Water Division assigned to evaluate the local geology and hydrogeology and to inspect the groundwater monitoring system. Duplicate samples were offered to and accepted by Mr. George Weiss.

The comprehensive groundwater inspection comprised two major aspects: a relative elevation survey of the groundwater monitoring system and a sampling program involoving the four ground water monitoring wells. The inspection was conducted in order to determine if the facility is complying with the Federal and State groundwater monitoring regulations and standards. The data generated from analysis of groundwater samples are included in the back of this report, as are the data from the relative elevation survey portion of this inspection.

The comprehensive groundwater inspection was performed at the request of Mrs. Margaret M. Corey of the Hazardous Waste Branch of ADEM. The geological review and groundwater assessment portions will be forthcoming and are furnished by Fred Mason of the Groundwater Section, Water Division, of ADEM.

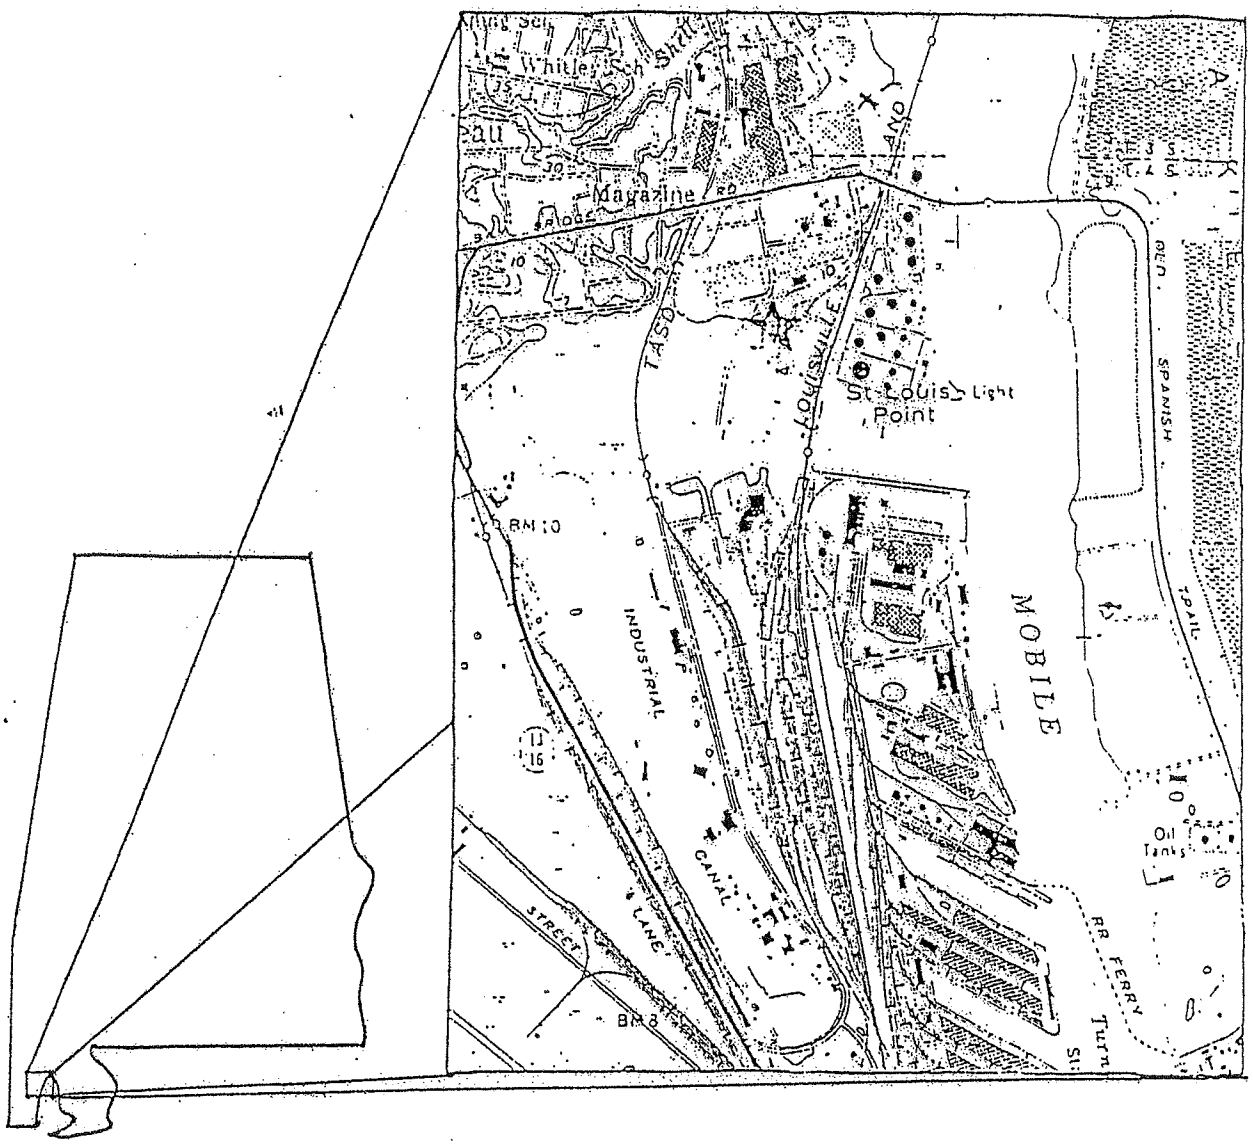

Figure 1

Facility Location Map
Cavenham Forest Products
Mobile, Alabama

BACKGROUND

The Crown Zellerbach Corporation operated a facility (Mobil Treated Woods Products) for the preservative treatment of wood products. The RCRA regulated hazardous waste management area consisted of an aeration pond and two concrete lined vacuum ponds. Crown Zellerbach installed approximately 30 wells to determine the rate, extent of migration, and the concentration of hazardous waste constituents in the groundwater. On May 5, 1986, Crown Zellerbach transferred the assets comprising the Mobile facility to Cavenham Forest Industries, Inc. Interim Status was also transferred. On June 4, 1986, EPA recieved the revised closure plan for the Cavenham facility. In the closure plan, Cavenham proposed to close the surface impoundments and sand filter beds by leaving the waste sludges in place. A cutoff wall would be installed to contain the closed area and a cover system placed on the closed area. The closure plan was public noticed in June 1986 and approved/modified March 11, 1987. Closure was to start within 60 days of recieving the approval notice. As of the date of this comprehensive groundwater monitoring evaluation, the site is still being reviewed for closing.

DATA AND ANALYTICAL RESULTS

The complete ADEM data is included in this report as a section of tables at the rear of the report.

RCRA Well Data

National Interim Primary Drinking Water Standards (NIPDWS)

These parameters were not sampled for during this inspection.

General Groundwater Quality Indicator Parameters

These parameters were not sampled for during this inspection.

Groundwater Contamination Indicator Parameters

The pH measurements obtained by Field Operations personnel were in the 4.75 - 10.85 standard unit range with pH's of 4.76 in Well UG-2, and 10.82 in Well B-25 (see Table 1).

The specific conductance measurements obtained were in the 180 to 1600 umho/cm range. Well B-1 had 180 umho/cm while Well B-56 had 1600 umho/cm (see Table 1).

In addition, Extractable Compounds data indicated the presence of the following contaminants (see Table 3):

Phenol in well B-29.
2,4-Dimethylphenol in well DG-1.
4-Nitrophenol in well DG-1.
Hexachloroethane in wells B-55, B-56, and B-57.
Naphthalene in wells B-56, B-57, and DG-1.
Acenaphthene in wells B-25, and DG-1.
2,4-Dinitrotoluene in wells B-19B, B-25, B-26.
Fluorene in well DG-1.

Phenanthrene in wells B-55, B-56, and B-57.
Anthracene in well B-55.

RELATIVE ELEVATION SURVEY

From the data recieved from the relative elevation survey, the upgradient well (MW-1) was measured as a relative water table elevation of 35.67 feet mean sea level (fmsl). All other wells measure less than 35.67 fmsl. See Table 2 for relative elevation data.

STUDY METHODOLOGY

All sample collection and sample handling techniques utilized during the acquisition of data for this comprehensive groundwater monitoring inspection were as described in the Field Operations Division Standard Operating Procedures and Quality Control Assurance Manual, Field Operations Division, ADEM, December 1986.

Laboratory analyses were performed by the ADEM Central Laboratory, Montgomery, Alabama. Chain-of-custody was maintained by locking samples in a State vehicle when not in sight of a Field Operations employee.

Re: Revised Post Closure Permit Application Attachments
Cavenham Forest Industries LLC
Mobile, AL
EPA I.D. ALD 057 226 904

Dear Ms. McCord:

On behalf of our client Cavenham Forest Industries LLC (CFI), Environmental Management Services, Inc. (EMS) is providing a response to ADEM's July 16, 2025 correspondence regarding differences between measured total well depths and the depths listed in the facility's RCRA Hazardous Waste Facility Permit.

The issue of depth discrepancies was first raised following the March 22, 2023 Operations and Maintenance inspection, as documented in ADEM's August 24, 2023 letter. At that time, it became evident that the permit-listed depths did not align with actual field measurements. Review of available construction records indicated that many of the historic values were inaccurate — often recorded from ground surface rather than top of casing (TOC), or in some cases based on estimated values or drillers records rather than verified construction data.

In response, the facility initiated a sitewide monitoring well inspection and maintenance measures project to ensure accurate depth records for all wells. This work was conducted between August 2023 and April 2024 in order to specifically address ADEM's concerns and fulfill RCRA Permit Conditions III.B.1.a and III.B.1.a.i.

These measures involved the following steps:

1. **Pump Removal for Full Access** – Pumps were removed from each monitoring and recovery well where present using a boom truck or carry deck crane, allowing unobstructed access for measurement.
2. **Initial TOC-Based Measurement** – Each well was measured from the top of casing to the bottom to the nearest 0.01 foot. These measurements were then compared to permit-listed depths and historic construction diagrams.
3. **Well Redevelopment** – Wells showing evidence of sediment accumulation were agitated and pumped using an air-driven pump and compressor. Sediment was removed and containerized for appropriate handling and disposal.
4. **Post-Redevelopment Measurement** – Following cleaning, wells were re-measured to verify that depth had been restored to original construction conditions.

5. **Downhole Camera Inspections** – Wells with significant or unexplained variances were video-inspected to confirm casing integrity and identify obstructions. No casing damage or significant structural defects were observed.
6. **Plumbing Improvements** – Where applicable, rigid drop pipe was replaced with flexible tubing to allow future redevelopment and maintenance without heavy equipment mobilization.
7. **Data Reconciliation** – All final post-redevelopment measurements were reviewed against available boring logs and construction diagrams to determine accurate "revised original" depths measured from TOC.

This investigation confirmed that the discrepancies were due primarily to inaccurate historic records or minor sediment accumulation, both of which have now been addressed.

Following completion of the sitewide field work and subsequent to ADEM's 2025 on-site inspection conducted by Ms. Marwa Sabeeh, EMS was contacted by Mr. Robert B. Stanley (ADEM) on May 12, 2025 regarding discrepancies noted between field-measured well depths and those listed in the facility's permit. In response, each well was re-measured using TOC reference points to confirm that they matched the "revised original" well depths previously established through redevelopment and inspection activities. All wells were found to be in compliance with these "revised original" depths, with the following exceptions: RW-3A, RW-3B, RW-4, RW-5, RW-11, RW-12, and RW-13, which could not be accurately measured due to the presence of pumps; and B-24, B-60A, and UG-2, which were found to contain sediment which had accumulated since the last well cleaning. The sediment-affected wells were subsequently cleaned, re-measured, and were found to be consistent with the "revised original" well depths. B-24 incorporates a two-foot "natural sump" which was installed in a sand/silty clay and requires higher maintenance than wells which contain traditional sumps. The exact well construction of B-60A and UG-2 are unknown, as only boring logs without well construction details exist in the site database.

Following this verification, Mr. Stanley recommended incorporating the corrected measurements into the permit renewal application to replace the inaccurate historic records. This recommendation was then communicated to Ms. Sabeeh, and the revisions were made accordingly to the Groundwater Monitoring and Remediation Well Construction Summary tables in Attachment P and Attachment R of the most recent revised Post Closure Permit Application, which was submitted on July 11, 2025.

After incorporation of the revisions, Ms. Sabeeh requested additional clarification similar to the questions presented in ADEM's July 16, 2025 correspondence. The history of the measurement discrepancies, the comprehensive field verification process, and the rationale for replacing the original well depths with the proposed "revised original" TOC-based depths were discussed in a phone call on July 30, 2025, and the decision was made to draft a letter summarizing previous inquiries and steps taken to identify and correct discrepancies with original well construction data. This letter will be included in the revised permit application as rationale for use of the proposed "revised original" well depths.

In the updated RCRA Hazardous Waste Facility Permit application, the facility will:

- Include the corrected "revised original" TOC-based depths in Table P-1.
- Provide an explanation of the discrepancies between previous permit records and the revised depths.
- Submit all available boring logs and well construction diagrams for permitted wells.

EMS believes the work completed fully addresses the concerns outlined in the July 16, 2025, letter and ensures that ADEM has an accurate record of the facility's monitoring well network going forward. Following the revisions listed above to the RCRA Hazardous Waste Facility Permit, this recurring issue regarding facility well depths should be resolved. If you have any questions or require additional information, please call either Collin R. Creel or Chris Johnson at (601) 544-3674.

Sincerely,
Environmental Management Services, Inc.

Collin R. Creel, P.G.
Project Geologist

1.0 INTRODUCTION

Cavenham Forest Industries LLC (CFI) maintains a closed hazardous waste facility in Mobile, Alabama that was used for preservative treating of wood products using pentachlorophenol and creosote. The wood treating operation has been terminated and the plant has been dismantled.

While the plant was operating, the facility maintained two hazardous waste surface impoundments: the two (2) Vacuum Ponds; and the Aeration Pond. These impoundments contained the listed hazardous waste K001 that is regulated by the Alabama Department of Environmental Management (ADEM). ADEM Administrative Code Rule 335-14-2 defines the K001 waste stream.

These surface impoundments were closed in place by dewatering, solidifying with lime kiln dust, and backfilling with waste from other onsite units. The waste was further encapsulated by encircling the area with a soil-bentonite slurry cutoff wall containing a vertical, high-density polyethylene (HDPE) liner, and covering with a cap composed of both natural clay and synthetic liners. Approximately twenty percent of the northern part of the Aeration Pond is not enclosed within the cutoff wall and this area is referred to as the north extension. The locations of the closed impoundments and the present hazardous waste management area (area of the closed landfill containing the former units) that will require groundwater monitoring during the post-closure period are indicated on the Groundwater Monitoring Well Locations map (Figure P-1).

This Groundwater Monitoring Plan (GWMP) describes the procedures for collecting, shipping and analyzing samples to satisfy the post-closure groundwater monitoring requirements contained in ADEM Administrative Code Rules 335-14-8-.02(5)(c)8.(iv).

The objective of the plan is to outline a groundwater monitoring program for this site and to define procedures that will effectively evaluate the groundwater corrective action that is occurring. Following a description of the groundwater monitoring system, the plan will focus on providing procedures, methodology and check lists that when followed, will assure the accurate collection of groundwater monitoring samples and field measurements.

CFI's Groundwater Monitoring Plan is organized into the following sections:

Section 2.0: Groundwater Monitoring System Description
Section 3.0: Monitoring Frequency and Parameters
Section 4.0: Sample Collection Procedures
Section 5.0: Sample Preservation, Shipment and Analysis
Section 6.0: Record Keeping
Section 7.0: Reporting
Section 8.0: Monitor Well Construction and Installation

2.0 GROUNDWATER MONITORING SYSTEM DESCRIPTION

CFI employs a separate groundwater monitoring system for each of two water-bearing soil horizons that underlie the Mobile facility. These groundwater monitoring systems monitor the groundwater quality in the shallow water-table aquifer, referred to as the "Upper Aquifer", and in a deeper massive sand horizon, referred to as the "Lower Aquifer". The locations of the monitoring wells in each of these aquifers are indicated on Figure P-1. Table P-1 provides a summary of construction details for each well.

2.1 Upgradient Monitoring Well

Monitoring well UG-2, which is located south of the office and north of the closure area (Figure P-1), will serve as the upgradient well. This well will be used as the upgradient well for both the Upper Aquifer and the Lower Aquifer since the confining clay aquitard is not present in this area and the two aquifers appear to be hydraulically connected.

2.2 Upper Aquifer Monitoring Wells

Monitoring wells RC-1, RC-2, RC-3 and RW-1 will serve as compliance monitoring wells for the Upper Aquifer. Monitoring wells RC-1, RC-2 and RC-3 are downgradient of the closure area, and RW-1 is on the upgradient side in the vicinity of the north extension of the RCRA cap (Figure P-1).

2.3 Lower Aquifer Monitoring Wells

Monitoring wells RC-1A, RC-2A, RC-3A and RW-2 will serve as compliance monitoring wells for the Lower Aquifer. Monitoring wells RC-1A, RC-2A and RC-3A are downgradient of the closure area, and RW-2 is on the upgradient side in the vicinity of the north extension of the RCRA cap (Figure P-1).

2.4 Corrective Action Effectiveness Monitoring Wells

During the corrective action period, one monitoring well in the Upper Aquifer and three monitoring locations in the Lower Aquifer will be used to monitor the effectiveness of the corrective action at the Mobile site. Effectiveness monitoring well E-1 and recovery trenches T-1 and T-2 will be used to monitor the effectiveness of corrective action of the Upper Aquifer groundwater. Effectiveness monitoring wells RW-3A, RW-4, and RW-5 will be used to monitor the Lower Aquifer groundwater beneath the hazardous waste management area. Data from these wells together with data from the neighboring point of compliance wells and boundary wells will provide adequate data for contouring the contaminant plume. The locations of these wells are indicated on Figure P-1.

2.5 Piezometers

CFI will maintain a network of piezometers at the site to verify that the recovery system is effectively controlling the hydraulic gradients in the vicinity of the site. The locations of the piezometers are indicated on Figure P-1.

2.6 Plume Defining Boundary Wells

Monitoring wells B-97, B-108A, B-128, and E-2 will serve as contaminant plume defining boundary monitoring wells for the Upper Aquifer. Monitoring wells RW-3B, RW-8A, B-24, B-25, B-36, B-60A, B-65, and B-101 will serve as contaminant plume defining boundary monitoring wells for the Lower Aquifer. These wells are near the downgradient limits of the contaminant plumes and will be used to monitor the advancement or retraction of the plume. The locations of these wells are indicated on Figure P-1.

2.7 Recovery System

Following the implementation of the Corrective Action Plan (CAP) Addendum, the site will have a total of thirty-one (31) recovery wells, two (2) recovery trenches, and a gradient control system which is pumped from three (3) locations. Of these thirty-one (31) recovery wells, fifteen (15) wells are designated recovery wells with the other sixteen (16) wells performing dual roles such as recovery in addition to being a boundary, compliance, effectiveness, or injection well. Of the fifteen (15) designated recovery wells, two (2) of these recovery wells have not yet been installed but will be installed following the approval of the CAP Addendum in the locations of AS-3 and AS-4. The existing designated recovery wells are RW-6, RW-7, RW-8, RW-9, RW-10, RW-11, RW-12, RW-13, RW-18, RW-19, RW-36, RW-37, and RW-38. Wells which perform dual roles as both recovery and boundary wells are RW-3B and RW-8A. Wells which perform dual roles as both recovery and compliance wells are RC-2, RC-3, RW-1, and RW-2. Wells and trenches which perform dual roles as both recovery and effectiveness monitoring locations are wells E-1, RW-3A, RW-4, RW-5 and recovery trenches T-1 and T-2. Wells which perform dual roles as both recovery and injection wells are wells A-1 through A-6, which are currently not being operated as either recovery or injection wells. Also a part of the recovery system is the gradient control system sump which is pumped from three (3) locations, GC SUMP, CO-7, and CO-10. The recovery system wells, trenches, and the gradient control system are indicated on Figure P-1.

3.0 MONITORING FREQUENCY AND PARAMETERS

The groundwater monitoring parameters and monitoring frequencies used to evaluate the groundwater quality beneath the waste management area at CFI's Mobile site are specified below.

Table P-2 is a list of parameters that have been selected for analysis of the groundwater at the Mobile facility. This list is based on recommendations provided by ADEM during the permitting process for this facility. Attachment L of the Post-Closure Permit Application provides statistical summary information on groundwater monitoring results obtained during the time period January 1, 2004 through December 31, 2012.

3.1 Upgradient Monitoring Well

Groundwater samples collected from the upgradient monitoring well UG-2 will be analyzed annually. Well UG-2 will be analyzed annually for Table P-2 parameters.

3.2 Upper and Lower Aquifer Compliance Monitoring Wells

Groundwater samples collected from the Upper and Lower Aquifer compliance monitoring wells will be analyzed semi-annually for Table P-2.

3.3 Effectiveness Monitoring Wells

Groundwater samples collected from each effectiveness monitoring location will be analyzed for Table P-2 parameters semi-annually.

3.4 Plume Defining Boundary Wells

Groundwater samples collected from each boundary monitoring well will be analyzed for the parameters indicated in Table P-2 semi-annually.

3.5 Recovery System

Following the implementation of the CAP Addendum, the recovery system will include thirty-one (31) recovery wells, two (2) recovery trenches, and a gradient control system, which is pumped from three (3) locations. Of the thirty-one (31) recovery wells and two (2) recovery trenches, ten (10) of the wells and both of the recovery trenches have dual roles and are sampled as either boundary, compliance, or effectiveness monitoring locations. Additionally, six (6) of the thirty-one (31) recovery wells are designated as either recovery or injection wells and are currently not being operated as either. This leaves fifteen (15) recovery wells and the three (3) recovery locations from the gradient control system which will be sampled exclusively as part of the recovery system. Groundwater samples collected from each recovery system location will be analyzed for the parameters indicated in Table P-2 minus arsenic, chromium, lead, and nickel in the frequency described below. There will be a total of 18 recovery system monitoring locations which will be sampled on a rotating basis. Half (9) of the recovery locations will be sampled on even years and the other half (9) will be sampled on odd years such that all recovery locations will be sampled over the span of two years.

4.0 SAMPLE COLLECTION PROCEDURES

4.1 Equipment Inventory

An equipment inventory will be conducted prior to sampling to make certain that adequate sampling supplies are available. A sampling equipment checklist is provided in Table P-3. Immediately prior to each sampling event, the following procedures will be accomplished:

1. Prior to and after sampling each well; ancillary equipment that will come into contact with the groundwater in the well (measuring tape, meters, etc.), will be rinsed thoroughly with acetone or methanol (as needed) followed by washing with a low phosphate detergent and final rinsing with distilled water;
2. Conductivity and pH meters will be calibrated before each sampling event. Fresh standards will be obtained at least every six months; and
3. Sample containers will be cleaned and samples preserved (if necessary) according to the requirements listed in Section 5.0.

4.2 Well Site Preparation

Upon arriving at the well site, the protective casing will be unlocked and the well casing cap will be removed from the well. A vent hole in the cap has been installed to ensure that the water level remains at ambient barometric pressure. The preliminary information requested on the Groundwater Sampling Data Form, shown as Figure P-2, will be recorded at this time. Appropriate safety precautions will be taken and protective clothing worn as necessary for sample collection. When collecting groundwater samples from monitoring wells not equipped with dedicated submersible pumps, plastic sheeting will be placed around the well to protect sampling equipment from potential contamination. Plastic sheeting will be used routinely for temporary storage of equipment and sample containers during the sampling.

4.3 Water Level Measurement

The initial water level will be recorded to the nearest 0.01 feet using either an electronic water level indicator probe or steel measuring tape. The depth to water will be referenced to a small notch inscribed into the top of the well casing corresponding to the location where the initial casing elevation was surveyed. The procedure for determining the depth to water using a steel tape is described in Table P-4.

4.4 Total Well Depth Measurement

The total depth of the well will be recorded to the nearest 0.01 feet using either a weighted electrical probe or steel measuring tape. Wells equipped with dedicated pumps that prevent a total depth measurement will be measured during pump maintenance events. Similarly, wells containing measurable levels of oily contaminants will be measured only during maintenance events. The total depth will be determined relative to the top of the well casing by lowering the pre-cleaned weighted measuring device slowly to the bottom of the well and recording the reading at the notched reference point at the top of the well casing. This reading will be used in the calculation of the volume of stagnant (standing) water in the well casing and will provide a check on the integrity of the well. To identify siltation problems this measurement will be compared to the well construction data presented in Table P-1. If the level of silt accumulation exceeds the screen/sump interface, the total well depth should be determined again after purging to confirm that the silt accumulation was removed. If purging techniques are unable to remove accumulated silts, the well will be scheduled for redevelopment. Any monitoring well that develops a history of siltation problems, as revealed from a review of prior sampling data, will undergo additional testing to confirm the integrity of the casing. If the integrity of the monitoring well casing is determined to be compromised based on excessive siltation or breach of the well screen, casing, or well seal, the monitoring well will be replaced in accordance with procedures in Section 9.0 of this plan.

4.5 Evacuation of Standing Water

Standing water will be removed from the well casing before collecting groundwater samples. A minimum of three well volumes will be removed to ensure that a

representative groundwater sample from the aquifer will be obtained. The standing water volume will be calculated from the following formula:

$$V_w = 3.14 (L-H)r^2;$$

where: V_w = Volume of standing water (cubic feet)
H = The depth from the top of the casing to the initial water level (feet),
L = The total well depth (feet), excluding depth of sediment if present.
r = The inside well casing radius (feet)

The standing water will be removed using a mechanical pump, a dedicated in-situ pump or a dedicated bailer. Prior to removing the standing water with an external mechanical pump, new or decontaminated tubing will be installed on the pump in order to prevent cross contamination.

Bailers and other equipment will be cleaned after each use. Procedures for cleaning equipment are provided in the USEPA Region 4's Laboratory Services and Applied Science Division (LSASD). Monitoring wells that are screened in high-yield formations will be bailed or pumped from above the screen in the uppermost part of the water column to ensure that fresh water from the formation has replaced stagnant water. Monitoring wells will not be purged to dryness if the recharge rate causes the formation water to vigorously cascade down the sides of the well screen resulting in an accelerated loss of volatile constituents. A minimum of three standing water volumes will be removed from each well to ensure that a representative sample of the formation groundwater is obtained.

4.5.1 Field Parameter Measurement

Field parameters (including pH, specific conductance, temperature, and turbidity) will be recorded immediately prior to purging each monitoring well. In addition, one set of field parameters will be collected and evaluated after the approximate volume of water equating to one well volume has been evacuated from the well. Field parameters will continue to be collected and evaluated after evacuation of each additional well volume for at least three and up to five well volumes, and when the parameters have stabilized for pH, specific conductance, and temperature, and when the turbidity has either

stabilized or is below 10 Nephelometric Turbidity Units (NTUs) in accordance with the acceptable criteria stated in the Alabama Environmental Investigation and Remediation Guidance (AEIRG). As stipulated by AEIRG, stabilization has occurred after pH readings remain constant within 0.1 Standard Units (SU), specific conductance varies by no more than 10 percent, and temperature is constant for three consecutive readings. The field parameter measurement data will be documented on the Groundwater Sampling Data Form (Figure P-2).

Following removal of three to five standing water volumes and stabilization of the field parameter criteria, the groundwater samples will be collected using a mechanical pump, dedicated in situ pump, or dedicated bailer.

In the event a monitoring well is incapable of yielding three standing water volumes, the well will be evacuated to dryness, allowed to recover, and then evacuated to dryness a second time to ensure the removal of stagnant water. As soon as the well recovers the second time, pH, temperature and specific conductance measurements will be recorded, followed by filling the sample containers in the designated order listed in Section 4.6 of this plan.

All purge water will be collected and containerized at any monitoring well that the facility background data suggests has contamination. Collected purge water will be routed through the on-site recovered groundwater treatment system for “disposal”.

4.5.2 Instrument Maintenance and Repair

Instruments used in field parameter measurement for this sampling program are stored on site in the CFI-Mobile office. The instrument used is a Multi-Parameter meter that measures pH, conductivity, dissolved oxygen, and temperature. The instruments are maintained in accordance with the manufacturer’s schedules and specifications described in the instrument operation manuals. The instrument manuals are stored on site in the CFI-Mobile office with each instrument. A copy of the maintenance instructions is kept with the instrument at all times. The procedures for calibration, use, and maintenance are adhered to each time the equipment is used.

In the event of an equipment malfunction or failure, the nature of the malfunction will be recorded on the Groundwater Sampling Data Form, and the instrument will be tagged for maintenance or repair by the sampling personnel. Groundwater sampling operations will cease until the malfunction is corrected or an equivalent replacement instrument is obtained, calibrated, and deemed suitable for continuation of the sampling operations. CFI maintains additional field parameter measurement instruments in nearby facilities that may be accessed if required for timely resumption of the groundwater sampling activities.

4.6 Sample Collection

Groundwater sample collection at the CFI-Mobile facility is accomplished using various methods according to the design and purpose of the well. The wells at the CFI-Mobile facility can be described using the following general categories:

1. Active groundwater recovery wells with dedicated electric submersible pumps;
2. Inactive groundwater recovery wells with dedicated electric submersible pumps;
3. Active groundwater recovery wells with dedicated air-lift pumps;
4. Inactive groundwater recovery wells with dedicated air-lift pumps;
5. Groundwater monitoring wells with dedicated (remotely stored) PVC electric submersible pumps and disposable bailers.

Active groundwater recovery wells with dedicated electric submersible pumps and dedicated air-lift pumps are sampled by filling the appropriate containers from a valve installed within the pump's discharge line. Care is taken to reduce the flow of the groundwater through the valve to allow a slow, non-turbulent flow (less than 100 ml/minute) into the sample container(s).

Inactive groundwater recovery wells with dedicated electric submersible pumps are sampled in the same manner as the active recovery wells, however the pumps in these wells are activated only for the purging and sampling procedure. Prior to sampling, the pumps are allowed to run for a period of time necessary to obtain flow rate and

stabilization parameter information and calculate the time necessary to complete the purging procedure.

Inactive groundwater recovery or monitoring wells containing dedicated air-lift pumps are sampled by connecting a bottle of compressed nitrogen to the air line to activate the pump for the purging and sampling procedure. The nitrogen is used as a source of inert gas in order to prevent possible cross contamination from outside air or the air compressor components. Samples are collected in the same manner as active wells containing air-lift pumps, i.e., through an in-line valve opened to the point where a slow, non-turbulent flow is achieved (less than 100 ml/min).

Monitoring wells that contain no dedicated pumps installed in them are purged with remote, dedicated, Geosquirt™ 12-volt, submersible, plastic and stainless steel, centrifugal pumps capable of flow rates up to 2.5 gallons per minute. These dedicated purge pumps are stored in individual plastic containers inside the CFI-Mobile storeroom. The containers are labeled with the monitoring well designation for which each pump is dedicated. Upon completion of the purging and field parameter measurement process and removal of the purge pump, sampling of each of these wells is accomplished with a disposable PVC bailer. Each bailer is equipped with a bottom filling inlet and check valve assembly and a length of new nylon cord. Samples are collected by slowly lowering the bailer into the water column and allowing the bailer to fill gently. Upon retrieval of the bailer, the groundwater is poured slowly into the appropriate sample containers in a manner as to minimize turbulence.

Groundwater samples will be collected by filling the appropriate sample containers listed in Table P-5 directly from the dedicated pump discharge line or from the dedicated bailer as appropriate. Extreme care will be taken to minimize agitation of the sample during the transfer. The sample containers will be completely filled and sealed.

A general sampling order to be followed is presented below:

1. Volatile Organics;
2. Extractable Organics;
3. Metals; and
4. Other Constituents.

Immediately following collection, the groundwater samples will be placed in plastic bags and will be stored in ice chests containing ice or ice packs for shipment to the laboratory.

Any ice chests to be shipped will be strapped with packing tape to prevent opening during shipment. Custody seals will be placed on each ice chest to ensure the integrity of the samples during shipment. Chain-of-custody forms will be completed and placed in a sealable plastic bag and taped to the inside of the cooler lid for shipment or transport with the samples.

4.7 Field Analysis

Prior to analyzing each sample, the appropriate equipment will be calibrated, as necessary, according to the manufacturer's specifications and consistent with procedures outlined in Test Methods For Evaluating Solid Waste - Physical/Chemical Methods (SW-846). Measurements of pH, temperature and specific conductance will be performed in the field at the time of sampling. Subsequent to well evacuation, approximately one half-gallon of sample will be placed in a clean, glass container. The field tests performed on this sample. Values will be recorded on the Groundwater Sampling Data Form (Figure P-2).

Under no circumstance will monitoring probes be placed in the groundwater sample containers which will be submitted for laboratory analysis. Field measurements will not be performed on samples with non aqueous phase oily materials that may render the monitoring equipment useless for additional measurements. If encountered, this observation and justification for omitting the field parameter measurements will be thoroughly recorded on the Groundwater Sampling Data Form.

4.8 Equipment Decontamination Procedures

Equipment decontamination procedures will be accomplished in accordance with USEPA Region 4 LSASD requirements listed in Appendix B and Appendix C. These sections of the LSASD are included in this work plan as Exhibit P-1 for reference.

For field decontamination of large pieces of equipment, a decontamination pad will be constructed in accordance with LSASD requirements. The decontamination pad at the CFI-Mobile facility will be located adjacent or within (as practicable) the impermeable, bermed groundwater treatment unit to allow the fluids collected to be pumped into the treatment stream for remediation of any site related contaminants.

5.0 SAMPLE PRESERVATION, SHIPMENT AND ANALYSIS

5.1 Sample Preservation

Many of the chemical constituents and physiochemical parameters to be measured in the groundwater are not chemically stable and can be modified by processes such as microbiologic activity, degassing, hydrolysis, and sorption prior to analysis. Therefore, samples will not be exposed to excessive heat or sunlight in the field and the appropriate preservation will be used. Table P-5 summarizes the sample container and preservation requirements that will be followed.

5.2 Sample Shipment

After the samples have been collected, they will be placed in sealable plastic bags and will be stored on ice or ice packs for shipment to the laboratory by CFI representatives or by an overnight courier. The ice chests that will be transported or shipped from the site will be strapped with packing tape to prevent opening during shipment and custody seals will be attached to ensure integrity of the sample. A typical sample container label is presented as Figure P-3. Shipment of the samples to the laboratory will be performed with as few transfers as possible. All samples will remain cooled at 4˚C during shipment.

5.3 Sample Analysis and Laboratory Designation

The groundwater samples will be analyzed for the parameters listed in Table P-2 at the frequencies specified in Section 3.0. The designated laboratory for the sampling program at CFI-Mobile is Micro-Methods Laboratory, Inc. (Micro-Methods) located in Ocean Springs, MS.

The sample analysis methods indicated in Table P-6 are EPA approved and will be implemented with appropriate quality assurance/quality control procedures. Any deviation from an approved EPA method will be noted in the analytical report. Holding times for each parameter are specified in Table P-6.

5.4 Sample Containers

All groundwater samples will be placed in pre-cleaned containers supplied by the contract laboratory. These sample containers will be cleaned by the laboratory according to the laboratory's decontamination procedures. All preservatives will be added to the sample containers by the laboratory prior to shipment.

5.5 Quality Assurance Samples

To ensure an appropriate level of quality assurance and quality control in the sampling and analysis program at the CFI-Mobile facility, a number of quality assurance samples will be collected and analyzed. The quality assurance samples will include trip blanks and duplicate samples using the following rationale:

- **Trip blanks** - A laboratory-supplied trip blank, consisting of a set of volatile organic analysis containers (40 mL vials) filled with analyte-free water will accompany each cooler of samples scheduled for volatile organic compound (VOC) analysis. The trip blanks will be handled and treated in the same manner as the investigative samples collected for VOC analysis, and will be analyzed along with the samples in the same batch of samples transported in the same cooler. The trip blanks analyzed will evaluate whether the sample container transportation process may have affected the analytical result.

- **Duplicate/Replicate Samples** - To evaluate the repeatability of the analytical laboratory techniques and results, duplicate samples will be collected for each requested analytical parameter at the rate of one per sampling day or at a rate of 10% of the samples collected, whichever is greater. The duplicate samples will be collected in the same manner as the original sample, and will be labeled to conceal the identity of the monitoring well sampled (i.e., a "blind" duplicate).

In addition to the quality assurance samples described above, other quality assurance samples may be collected if necessary or required. The additional quality assurance samples and the rationale for their collection and analysis is described below:

- **Field Equipment Blanks** - The field sampling measures employed at the CFI-Mobile facility are designed specifically to avoid the necessity for decontamination of field equipment that would require the implementation of field equipment blanks to check for possible cross contamination of samples. CFI-Mobile accomplishes this through the use of dedicated sampling equipment for each monitoring well identified in this sampling program. Therefore, for routine monitoring well sampling the use of field equipment blanks will not be required. However, in cases where sampling with non-dedicated or previously used equipment may be implemented, an equipment rinsate blank will be required to be collected at the rate of one per sampling day or at a rate of 10% of the samples collected, whichever is greater. The equipment blank will be collected for VOC analysis only, and will be collected after standard field cleaning procedures have been accomplished in accordance with the EISOPQAM measures stipulated in Exhibit P-1. The field equipment blank will be collected in accordance with Section 5.13.10 of the EISOPQAM, by obtaining a sample of analyte free water poured over the surface of the cleaned piece of equipment.
- **Decontamination Water Samples** - As CFI-Mobile operates a groundwater treatment system capable of reducing the site contaminants to non-detectable levels as documented in the remediation system performance reports, decontamination water collected as a result of field cleaning operations will be transferred or pumped into the collection system of the groundwater treatment unit and treated along with the site contaminants collected in the groundwater recovery system. Any solid matter collected as a result of field decontamination operations will be transferred to the on-site Corrective Action Management Unit (CAMU) for treatment along with excavated soils from site cleanup operations or disposed at an appropriate disposal facility.

6.0 RECORD KEEPING

6.1 Sample Labels

Sample labels, which will be provided by the laboratory, will be used to prevent mis-identification of the samples. Prior to the delivery of the sample containers to CFI, the laboratory will identify, on the pre-affixed label, the analysis to be performed and the preservative included therein. The labels will be filled out at the time of collection using waterproof ink. The following information will be recorded on the labels:

1. Sample identification number;
2. Name of collector and company;
3. Date and time of collection;
4. Facility identification;
5. Preservative; and
6. Analysis to be performed.

The information contained in a typical sample label is presented as Figure P-3.

6.2 Groundwater Sampling Data Form

CFI will maintain a Groundwater Sampling Data Form that will be completed at the time of sampling. This form will provide a source of documentation to indicate that sampling requirements have been fulfilled and will provide a permanent record of field measurements, conditions, and observations. A Groundwater Sampling Data Form is presented as Figure P-2.

6.3 Chain-of-Custody

The sampler will complete the Chain-of-Custody form(s) to establish the documentation necessary to trace sample possession from the time of collection to the time of analysis. A typical Chain-of-Custody form is presented as Figure P-4. The field sampler will be responsible for the custody and care of collected samples until the containers have been transferred to the custody of the laboratory. At the time of sample collection, the chain-

of-custody form will be initiated by the field sampler. The form will be filled out in legible handwriting in ink and will be transported to the laboratory with the samples to be analyzed.

7.0 REPORTING

Groundwater monitoring data from the site's monitoring wells will be reported to the Regional Administrator in accordance with the applicable requirements of ADEM Administrative Code Rule 335-14-5-.06(8), 335-14-5-.06(9), 335-14-5-.06(10), and 335-14-5-.06(11).

7.1 Data Evaluation

When applicable, data evaluation procedures will consist of one of the statistical methodologies outlined within the ADEM Administrative Code Rule 335-14-5-.06(8). A description of the statistical methods (selected from approved methodologies listed) and associated procedures utilized to evaluate collected data will be provided within groundwater monitoring reports. Should CFI consider alternate statistical methods to evaluate data (not specified within ADEM Administrative Code Rule 335-14-5-.06(8)), CFI will recommend the alternate methodology to ADEM through correspondence and implement the recommended statistical procedures following ADEM approval.

7.2. Report

CFI will submit an annual groundwater monitoring report for the Mobile facility that will include the following information:

- The direction and rate of groundwater flow for the Upper Aquifer and Lower Aquifer;
- Monitoring data demonstrating the effectiveness of the Corrective Action Program;
- Routine groundwater monitoring data;
- An evaluation of the contaminant trend in monitor wells exhibiting groundwater contamination to determine if the concentration has increased or decreased;
- Copies of all original laboratory analytical reports with completed Chain-of-Custody forms;

- Maps illustrating the groundwater flow direction in the upper and lower aquifer zones;
- Plume delineation maps with the current dimensional interpretation;
- Trend plots and graphs illustrating concentration increases and decreases over time; and
- Legible copies of the Groundwater Sampling Data Forms.

8.0 MONITORING WELL CONSTRUCTION AND INSTALLATION

Construction techniques for the installation of the groundwater monitoring system at the Mobile facility are presented in the following sections. These construction techniques will be applied during the installation of the post-closure, monitoring well system and future replacement wells, if required. A typical construction diagram for an Upper Aquifer monitoring well is provided as Figure P-5. A typical construction diagram for a Lower Aquifer monitoring well is presented as Figure P-6. All well construction, installation, and abandonment procedures will follow the Alabama Environmental Investigation and Remediation Guidance Document (AEIRG) revision 4.0, dated February 2017.

8.1 Materials

The well casing, end plugs and caps for the CFI-Mobile groundwater monitoring system will consist of Schedule 5 Type 304 stainless steel with male and female, flush-thread, end fittings. The well screen will be the same diameter as the well casing and will consist of 0.010-inch (#10 slot) continuous, V-slot, Type 304 stainless steel with male and female, flush-thread, end fittings. Groundwater monitoring wells will typically be "2-inch diameter" wells. The typical monitoring well screen will be the "2P**" pipe size, "W90 Construction" type (2.41 in. OD x 1.99 in. ID) as indicated on the US Filtration & Separations Small Diameter Well Screens specification sheet in Exhibit P-3.

Stainless steel centralizers will be used during the construction of all of the Lower Aquifer wells. Centralizers will be the "clamp-on" type, manufactured from Type 304 stainless steel.

Surface isolation casing, if required, will be 10-inch diameter, carbon steel. The surface isolation casing will be installed into a competent clay formation and grouted using the tremie method from the bottom to the top on the exterior (annulus) and interior of the casing. After the grout surrounding the casing has hardened for a minimum of 24 hours, the interior of the casing will be re-drilled to install a 2-inch diameter monitoring well screen and casing well into the target formation.

The sand pack will consist of rounded filter sand of 20/40 grading, manufactured specifically for the intended purpose. The sand pack will be installed using the tremie method to ensure the sand completely encompasses the well screen and no bridging has occurred in the installation. A weighted tape will be used to continually check the depth and progress of the sand pack installation.

An approximately two-foot thick bentonite well seal will be installed using 1/4-inch diameter pellets that are manufactured of basic sodium bentonite. The sodium bentonite pellets will be hydrated with tap water or formation water and allowed to continue hydration for approximately 24 hours prior to the introduction of the grout material described below.

Cement/bentonite grout will be composed of Type I Portland cement with not more than 9 gallons of water added per 94 pounds of cement. (13.5# mix.). To this mixture, 3% by weight of basic bentonite gel will be added and thoroughly mixed. The grout will be installed via the tremie method from the bottom to the top of the well casing.

8.2 Soil Borings

Soil borings will be drilled using either the rotary wash, solid-stem auger, or hollow-stem auger drilling method(s). The rotary-wash drilling method will be used for all monitoring wells completed in the deeper zone. All of the drilling equipment and tools will be steam cleaned and rig pumps will be flushed with potable water prior to mobilizing on site and prior to initiating drilling activities or returning to any boring or well location.

Prior to initiating drilling at each borehole, the ground surface around the proposed location will be cleared of any brush or other natural organics and, if present, any ponded surface water will be drained. A carbon-steel surface casing will then be pushed into the ground one (1) to two (2) feet, with no less than six (6) inches of stick-up.

Split-spoon soil samples will be collected continuously to a maximum depth of 50 feet. Below 50 feet, the samples will be collected on five-foot centers or whenever strata changes are noted. All of the samples will be logged by an experienced geologist or engineer. Each soil sample will be visually described in accordance with the Unified Soil

Classification System and any evidence of contamination will be clearly noted on the boring log.

If shallow (Upper Aquifer) contamination is encountered during the installation of the Lower Aquifer monitoring wells, a carbon-steel, surface-isolation casing will be installed from the ground surface and will be seated at least one foot (12-inches) into the clay aquitard that separates the Upper and Lower Aquifer. The surface isolation casing will be pushed into the clay layer and the area between the casing and the borehole will be grouted to the ground surface with cement grout. Care will be exercised not to fully penetrate the clay aquitard with surface isolation casing.

The casing grout will be allowed to cure for a minimum of 24 hours prior to further advancing the borehole. After the grout has cured, the casing interior will be washed with clean water to remove soil and mud. Circulation of clean water will continue until clear water is returned. Before commencing with the drilling activities, all of the drilling equipment, tools and pumps will be decontaminated in accordance with Section 8.4. Contaminated water and cuttings that may be generated, will either be treated on-site through the active groundwater treatment system and the CAMU (for soils, if the CAMU is active), or will be drummed for off-site disposal at an approved disposal facility.

8.3 Well Installation

The geologist or engineer will determine in the field where to terminate the boring and where to set the well screen, based on the boring log. Prior to installing the well casing, the entire length of the boring will be reamed to the appropriate diameter to accommodate the well screen and the sand pack. After completion of the reaming, the drilling fluid will be removed from the borehole using clean water. Slow circulation of clean water will continue until returns are clear.

All well material will be steam cleaned prior to assembly. The well screen and casing will be assembled (or partially assembled) on a portable pipe rack or in some similarly clean location. The screen length will correspond to, or will be slightly less than, the thickness of the monitored zone. The bottom of the screen will be placed within zero (0) to one (1) foot above the bottom of the monitored zone. Stainless-steel centralizers will be placed

near the end plug or the sump and will also be placed five (5) feet above the top of the well screen. Metal or PVC centralizers will be placed every fifteen (15) feet thereafter. There shall be a minimum of two (2) centralizers on each well. Care will be exercised to keep all well construction materials clean and free of dirt, oil, grease and other extraneous contaminants prior to and during installation. Clean water will be gently circulated through the assembled well after it has been placed into the borehole.

The sand pack will be placed after the well pipe has been installed. The sand pack will extend from the bottom of the borehole to one to three feet above the top of the screen. The sand will be slowly placed into the annular space to prevent bridging. Two feet of bentonite pellets will be installed on top of the sand pack. The depths to the top of the sand and bentonite plug will be determined with a weighted measuring tape. The remaining annular space will be tremie grouted from the top of the bentonite plug to the ground surface after allowing approximately 24 hours for hydration of the bentonite. Pumping of grout will continue until a thick grout is returned to the surface.

8.4 Drill Rig Decontamination

To prevent cross contamination between boreholes, the drill rig will be decontaminated at the following times during the course of the project:

- Upon arrival at the site;
- Prior to initiating a new boring or returning to a partially completed boring; and
- Prior to leaving the site.

Decontamination will be performed in accordance with LSASD procedures, and will generally consist of steam cleaning of the rear of the drill rig (table, tires, bottom of the mast, etc.), the mud pit, the surface casing, all of the unclean drill stem (inside and outside), and all of the down-hole tools. Clean water will also be circulated through the pump and hose until it runs clear.

8.5 Well Development and Testing

Each well will be allowed to set for a minimum of 48 hours after grouting prior to beginning well development. The wells will be developed using air-lift techniques to ensure that the following completion criteria are satisfied: 1) any remaining drilling fluids introduced into the well are removed, 2) hydraulic contact is established between the well bore and the formation, and 3) the formation surrounding the screen has been stabilized. Development will continue until clear formation water is pumped from the wells, and stabilization criteria have been met for three (3) consecutive readings over several minutes. The stabilization criteria will include pH (≤0.1 Standard units), Specific Conductance (≤ 10%), and turbidity (<5 NTUs). If the stabilization parameters are not met after initial development efforts on a well, the well development process may be repeated as necessary to attempt to achieve compliance with the field parameter criteria. As the formation may not yield turbidity down to the acceptable criterial even with substantial development efforts, the determination of the suitability of the well installation will rest with the project manager and field supervisor.

Slug tests will be performed on each monitoring well installed to estimate the hydraulic conductivity of the screened zone. Both falling and rising head tests will be performed. The tests may utilize water withdrawal and addition or a volume displacement method (for rising and falling-head tests, respectively). Any slug or water added to the well will be clean and free of contaminants.

8.5 Well Abandonment Procedures

When a decision is made to abandon a monitoring well, either for closure purposes or if the well construction integrity has been compromised, the borehole shall be sealed in accordance with procedures outlined in EISOPQAM Section 6.9, and in general accordance with ADEM Administrative Code R.335-9-1.06 (g). For shallow monitoring wells, abandonment may be accomplished by either over-drilling the well casing and borehole then filling the clean borehole with the appropriate grout material, or in the case of deep or large diameter monitoring wells the well screen and casing will be pressure grouted from the bottom to the top using the tremie method.

SAMPLING EQUIPMENT CHECKLIST
Cavenham Forest Industries LLC Mobile, Alabama

EQUIPMENT

- Water level indicator
- Multi-Parameter Field Meter
- pH Meter
- Specific Conductance Meter
- Thermometer
- Hand or Mechanical Pump (with supply of tubing), or bottom filling bailer for each well, and an appropriate length of clean rope
- Appropriate number of sample containers per well
- Preservatives

Miscellaneous Items

- Distilled water
- Acetone or methanol
- Wash bottles
- Paper towels
- Plastic sheeting
- Ice chest
- Ice or freezer packs
- Sampling labels
- Sampling forms, clipboard, pen
- Chain-of-Custody forms
- Graduated bucket
- Garbage bags
- Containers for contaminated purge water and equipment contamination
- Sealable Plastic bags
- Batteries
- Cell Phone (Camera, Communication Device)

TABLE P-4
DEPTH TO WATER MEASUREMENT
Cavenham Forest Industries LLC Mobile, Alabama

If a steel measuring tape is used, the water level measurement will proceed in the following order:

- The measuring tape will be rinsed with distilled water and dried with a clean cloth.
- Chalk will be applied to the bottom two feet of the tape.
- The weighted tape will be lowered slowly down the center of the well casing.
- After the water is encountered in the well, the tape will be held at the closest even foot marker at the top of the well casing.
- The "held" measurement is recorded.
- The tape will be reeled out of the well.
- The measurement where the tape became wet is recorded.
- Depth to water is found by subtracting the "wet" measurement from the "held" measurement.
- Water level elevation relative to mean sea level is found by subtracting the depth to water from the top of casing elevation.

GROUNDWATER LEVEL AND WELL DEPTH MEASUREMENTS

(LSASDPROC-105-R4)

Region 4 U.S. Environmental Protection Agency Laboratory Services and Applied Science Division Athens, Georgia	
Operating Procedure	
Title: Groundwater Level and Well Depth Measurement	ID: LSASDPROC-105-R4
Issuing Authority: LSASD Field Branch Chief	
Effective Date: May 15, 2020	Review Date: May 15, 2024

Purpose

This document describes general and specific procedures, methods and considerations to be used and observed when determining water levels and depths of wells.

Scope/Application

The procedures contained in this document are to be used by field investigators to measure water levels and depths of wells. On the occasion that LSASD field investigators determine that any of the procedures described in this section are either inappropriate, inadequate or impractical and that another procedure must be used for water level or depth determination, the variant procedure(s) will be documented in the field log book and the subsequent investigation report, along with a description of the circumstances requiring its use

1 General Information

1.1 Documentation/Verification

This procedure was prepared by persons deemed technically competent by LSASD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the LSASD Local Area Network. The Document Control Coordinator is responsible for ensuring the most recent version of the procedure is placed on the LAN and for maintaining records of review conducted prior to its issuance.

1.2 General Precautions

1.2.1 Safety

Proper safety precautions must be observed when measuring water levels in wells and determining their depths. Refer to the LSASD Safety, Health and Environmental Management Program Procedures and Policy Manual and any pertinent site-specific Health and Safety Plans (HASPs) for guidelines on safety precautions. These guidelines, however, should only be used to complement the judgment of an experienced professional. Address chemicals that pose specific toxicity or safety concerns and follow any other relevant requirements, as appropriate.

1.2.2 Procedural Precautions

The following precautions should be considered when measuring water levels and depths of wells:

- Special care must be taken to minimize the risk of cross-contamination between wells when conducting water level and depth measurements. This is accomplished primarily by decontaminating the sounders or other measuring devices between wells, according to LSASD Operating Procedure for Field Equipment Cleaning and Decontamination, (LSASDPROC-205) and maintaining the sounders in clean environment while in transit between wells.
- Water levels and well depths measured according to these procedures should be recorded in a bound logbook dedicated to the project as per LSASD Operating Procedure for Logbooks (LSASDPROC-010). Serial numbers, property numbers or other unique identification for the water level indicator or sounder must also be recorded.

2 Quality Control Issues

There are several specific quality control issues pertinent to conducting water level and depth measurements at wells. These are:

Uncontrolled When Printed

- Devices used to measure groundwater levels should be verified annually against a National Institute of Standards and Technology (NIST) traceable measuring tape. These devices should check to within 0.01 feet per 10 feet of length with an allowable error of 0.03 feet in the first 30 feet. Before each use, these devices should be prepared according to the manufacturer's instructions (if appropriate) and checked for obvious damage. All verification and maintenance data should be documented electronically or recorded in a logbook maintained at the Field Equipment Center (FEC) as per the LSASD Operating Procedure for Equipment Inventory and Management (LSASDPROC-108). The functional check and tape length verification should be performed according to the instructions included in LSASDFORM-043, *Well Sounder Function Check and Verification,* which also includes the form for recording the required information.

- These devices should be decontaminated according to the procedures specified in LSASD Operating Procedure for Field Equipment Cleaning and Decontamination (LSASDPROC-205) prior to use at the next well.

3 Water Level and Depth Measurement Procedures

3.1 General

The measurement of the groundwater level in a well is frequently conducted in conjunction with ground water sampling to determine the phreatic water surface. This potentiometric surface measurement can be used to establish ground water direction and gradients. Groundwater level and well depth measurements are needed to determine the volume of water or drawdown in the well casing for proper purging.

All groundwater level and well depth measurements should be made relative to an established reference point on the well casing and should be documented in the field records. This reference point is usually identified by the well installer using a permanent marker for PVC wells, or by notching the top of casing with a chisel for stainless steel wells. By convention, this marking is usually placed on the north side of the top of casing. If no mark is apparent, the person performing the measurements should take both water level and depth measurements from the north side of the top of casing and note this procedure in the field log book.

To be useful for establishing groundwater gradient, the reference point should be tied in with the NAVD88 (North American Vertical Datum of 1988) or a local datum. For an isolated group of wells, it is acceptable to use an arbitrary datum common to all wells in that group.

Water levels should be allowed to equilibrate prior to measurement after removing sealing caps. There are no set guidelines and appropriate equilibration times can range from minutes to hours depending on well recharge, local geology and topography, and project objectives.

Uncontrolled When Printed

3.2 Specific Groundwater Level Measurement Techniques

Measuring the depth to the phreatic ground water surface can be accomplished by the following methods. Method accuracies are noted for each of the specific methods described below.

- Electronic Water Level Indicators – These types of instruments consist of a spool of dual conductor wire, a probe attached to the end and an indicator. When the probe comes in contact with the water, the circuit is closed and a meter light and/or audible buzzer attached to the spool will signal contact. Penlight or 9-volt batteries are normally used as a power source. Measurements should be made and recorded to the nearest 0.01 foot.

- Other Methods – There are other types of water level indicators and recorders available on the market, such as weighted steel tape, chalked tape, sliding float method, air line pressure method and automatic recording methods. These methods are primarily used for closed systems or permanent monitoring wells. Acoustic water level indicators are also available which measure water levels based on the measured return of an emitted acoustical impulse. Accuracies for these methods vary and should be evaluated before selection. Any method not capable of providing measurements to within 0.1 foot should not be used.

3.3 Special Considerations for Water Level Measurements at Sites with Shallow Groundwater Gradient

Groundwater gradients at some sites can be very shallow and if gradient and groundwater flow pattern (gradient direction) determination are part of the project objectives, it is critical that groundwater level measurements obtained from wells are as accurate as possible. Special care should be taken to allow the water level to equilibrate after removing sealing caps and the same sounder should be used for all measurements, if possible. The sounding activity should be coordinated to allow all wells to be sounded within the minimum possible time. This is particularly important in areas with potential tidal influences.

3.4 Total Well Depth Measurement Techniques

The well sounder, weighted tape or electronic water level indicators can be used to determine the total well depth. This is accomplished by lowering the tape or cable until the weighted end is felt resting on the bottom of the well. Because of tape buoyancy and weight effects encountered in deep wells with long water columns, it may be difficult to determine when the tape end is touching the bottom of the well and sediment in the bottom of the well can also make it difficult to determine total depth. Care must be taken in these situations to ensure accurate measurements. The operator may find it easier to allow the weight to touch bottom and then detect the 'tug' on the tape while lifting the weight off the well bottom. All total depth measurements must be made and recorded to the nearest 0.1 foot. As a cautionary note, when measuring well depths with the electronic water level indicators, the person performing the measurement must measure and add the length of the probe beneath the circuit closing electrodes to the depth measured to obtain the true depth. This is necessary because the tape distance markings are referenced to the electrodes, rather than the end of the probe. For electronic sounders maintained at the LSASD FEC, the sounder reel will be marked with the appropriate additional length identified as the 'TD adder'.

Uncontrolled When Printed

3.5 Equipment Available

The following equipment is available for ground water level and total depth measurements:

- Weighted steel measuring tapes
- Electronic water level indicators

4 Establishment of Top of Casing Elevations

To establish groundwater surface elevations, the measured distance from the top of casing to the water surface is subtracted from the well top of casing (TOC) elevation. Obtaining accurate TOC elevations is crucial to developing an accurate groundwater surface elevation map and determination of groundwater flow direction.

The only acceptable means of surveying well TOC elevations is differential leveling conducted to third order standards. Third order differential leveling has allowable error defined by the following formula:

$$Allowable\ Error\ (ft) = 0.05 \times \sqrt{Survey\ loop\ length\ (miles)}$$

This work must be conducted with an auto level as the leveling instrument. Surveying TOC elevations with a total station or survey-grade GPS will not provide the requisite accuracy.

When adding wells to a monitoring network, it is permissible to tie the new well elevations to the known TOC elevations of existing wells in the network. The elevations of several wells in the existing network should be checked to assure that the relative differences in elevation match the recorded elevation data.

Generally, the ground surface elevations at each well should be surveyed at the same time.

1 General Information

1.1 Purpose

This document describes general and specific procedures, methods and considerations to be used and observed when collecting groundwater samples for field screening or laboratory analysis.

1.2 Scope/Application

The procedures contained in this document are to be used by field personnel when collecting and handling groundwater samples in the field. On the occasion that SESD field personnel determine that any of the procedures described are either inappropriate, inadequate or impractical and that another procedure must be used to obtain a groundwater sample, the variant procedure will be documented in the field logbook, along with a description of the circumstances requiring its use. Mention of trade names or commercial products in this operating procedure does not constitute endorsement or recommendation for use.

1.3 Documentation/Verification

This procedure was prepared by persons deemed technically competent by SESD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the SESD Local Area Network (LAN). The Document Control Coordinator (DCC) is responsible for ensuring the most recent version of the procedure is placed on the LAN and for maintaining records of review conducted prior to its issuance.

1.5 General Precautions

1.5.1 Safety

Proper safety precautions must be observed when collecting groundwater samples. Refer to the SESD Safety, Health and Environmental Management Program (SHEMP) Procedures and Policy Manual and any pertinent site-specific Health and Safety Plans (HASP) for guidelines on safety precautions. These guidelines, however, should only be used to complement the judgment of an experienced professional. The reader should address chemicals that pose specific toxicity or safety concerns

COPY

and follow any other relevant requirements, as appropriate.

1.5.2 Procedural Precautions

The following precautions should be considered when collecting groundwater samples.

- Special care must be taken not to contaminate samples. This includes storing samples in a secure location to preclude conditions which could alter the properties of the sample. Samples shall be custody sealed during long-term storage or shipment.
- Always sample from the anticipated cleanest, i.e., least contaminated location, to the most contaminated location. This minimizes the opportunity for cross-contamination to occur during sampling.
- Collected samples must remain in the custody of the sampler or sample custodian until the samples are relinquished to another party.
- If samples are transported by the sampler, they will remain under his/her custody or be secured until they are relinquished.
- Chain-of-custody documents shall be filled out and remain with the samples until custody is relinquished.
- Shipped samples shall conform to all U.S. Department of Transportation (DOT) rules of shipment found in Title 49 of the Code of Federal Regulations (49 CFR parts 171 to 179), and/or International Air Transportation Association (IATA) hazardous materials shipping requirements found in the current edition of IATA's Dangerous Goods Regulations.
- Documentation of field sampling is done legibly, completely, and neatly in a bound logbook.

COPY

2 Special Sampling Considerations

2.1 Volatile Organic Compounds (VOC) Analysis

Groundwater samples for VOC analysis must be collected in 40 ml glass vials with Teflon® septa. The vial may be either pre-preserved with concentrated hydrochloric acid or they may be unpreserved. Preserved samples have a two-week holding time, whereas unpreserved samples have only a seven-day holding time. In the majority of cases, the preserved vials are used to take advantage of the extended holding time. In some situations, however, it may be necessary to use the unpreserved vials. For example, if the groundwater has a high amount of dissolved limestone, i.e., is highly calcareous, there will likely be an effervescent reaction between the hydrochloric acid and the water, producing large numbers of fine bubbles and rendering the sample unacceptable. In this case, unpreserved vials should be used and arrangements confirmed with the laboratory to ensure that they can accept the unpreserved vials and meet the shorter sample holding times.

The samples should be collected with as little agitation or disturbance as possible. The vial should be filled so that there is a meniscus at the top of the vial and no bubbles or headspace should be present in the vial after it is capped. After the cap is securely tightened, the vial should be inverted and tapped on the palm or knuckle to check if any undetected bubbles are dislodged. If a bubble or bubbles are present, the vial should be topped off using a minimal amount of sample to re-establish the meniscus. Care should be taken not to flush any preservative out of the vial during topping off. If, after topping off and capping the vial, bubbles are still present, a new vial should be obtained and the sample re-collected. While the 8260 method allows for bubbles up to 6 mm at the time of analysis, dissolved or entrained gases can coalesce during shipment. Collecting VOC vials absent of bubbles is generally feasible and is a reasonable precaution.

2.2 Special Precautions for Trace Contaminant Groundwater Sampling

- Sampling equipment must be constructed of Teflon® or stainless steel materials. Bailers and pumps should be of Teflon® and stainless steel construction throughout.
- New Teflon® tubing should be used at each well, although tubing dedicated to a particular well may be reused, either after decontamination or storage in the well between sampling events. Caution is appropriate in reusing tubing where early sampling events report high concentrations of contaminants.
- A clean pair of new, non-powdered, disposable gloves will be worn each time a different location is sampled and the gloves should be donned immediately prior to sampling. The gloves should not come in contact with the media being sampled and should be changed any time during sample collection when their cleanliness is compromised.
- Sample containers for samples suspected of containing high concentrations of contaminants shall be stored separately.

COPY

- Sample collection activities shall proceed progressively from the least suspected contaminated area to the most suspected contaminated area if purging and sampling devices are to be reused. Samples of waste or highly contaminated media must not be placed in the same cooler as environmental (i.e., containing low contaminant levels) or background samples.
- If possible, one member of the field sampling team should take all the notes and photographs, fill out tags, etc., while the other members collect the samples.
- Clean plastic sheeting will be placed on the ground at each sample location to prevent or minimize contaminating sampling equipment by accidental contact with the ground surface.
- Samplers must use new, verified certified-clean disposable or non-disposable equipment cleaned according to procedures contained in SESD Operating Procedure for Field Equipment Cleaning and Decontamination (SESDPROC-205) or SESD Operating Procedure for Field Equipment Cleaning and Decontamination at the FEC (SESDPROC-206) for collection of samples for trace metals or organic compound analyses.

2.3 Sample Handling and Preservation Requirements

1. Groundwater samples will typically be collected from the discharge line of a pump or from a bailer. Efforts should be made to reduce the flow from either the pump discharge line or the bailer during sample collection to minimize sample agitation.

2. During sample collection, make sure that the pump discharge line or the bailer does not contact the sample container.

3. Place the sample into appropriate, labeled containers. Samples collected for VOC, and alkalinity analysis must be collected without headspace. All other sample containers must be filled with an allowance for ullage.

4. All samples requiring preservation must be preserved as soon as practically possible, ideally immediately at the time of sample collection. If pre-preserved VOC vials are used, these will be preserved with concentrated hydrochloric acid by Analytical Services Branch (ASB) personnel prior to departure for the field investigation. For all other chemical preservatives, SESD will use the appropriate chemical preservative generally stored in an individual single-use vial as described in the SESD Operating Procedure for Field Sampling Quality Control (SESDPROC-011). The adequacy of sample preservation will be checked after the addition of the preservative for all samples except for the samples collected for VOC analysis. If additional preservative is needed, it should be added to achieve adequate preservation. Preservation requirements for groundwater samples are found in the USEPA Region 4 Analytical Services Branch Laboratory Operations and Quality Assurance Manual (ASBLOQAM), most recent version.

COPY

5. Sample containers should be placed in an ice-filled cooler as soon as possible after filling. Ice in coolers should be in bags with minimal pooled water and the cooler should be periodically checked and replenished to maintain sample storage temperature.

2.4 Quality Control

Equipment blanks should be collected if equipment is field cleaned and re-used on-site or if necessary to document that low-level contaminants were not introduced by pumps, bailers, tubing, or other sampling equipment.

Where appropriate, a background sample upgradient of all known influences or a control sample upgradient of site influences may be indicated. Background and control samples should be collected as close to the sampled area as possible and from the same water-bearing formation as the site samples.

2.5 Records

Information generated or obtained by SESD personnel will be organized and accounted for in accordance with SESD records management procedures found in SESD Operating Procedure for Control of Records, SESDPROC-002. Field notes, recorded in a bound field logbook, will be generated, as well as chain-of-custody documentation in accordance with SESD Operating Procedure for Logbooks, SESDPROC-010 and SESD Procedure for Sample and Evidence Management, SESDPROC-005.

COPY

3 Groundwater Purging and Sampling

3.1 Overview of Purging and Sampling Strategies

Purging is the process of removing stagnant water from a well, immediately prior to sampling, causing its replacement by groundwater from the adjacent formation that is representative of aquifer conditions. Sampling is the process of obtaining, containerizing, and preserving (when required) a ground water sample after the purging process is complete. There are several approaches to well purging and sampling that may be appropriate in various circumstances or for various combinations of available equipment. They are briefly summarized below and in *Table 1, Purge and Sample Strategies with Equipment Considerations.*

The **Multiple-Volume Purge** method involves removing a minimum of three well volumes of water from the top of the water column and then sampling when the well has achieved stability of water quality parameters and adequately low turbidity. This is a traditional method and consistent results are generally obtained with samplers of varying skill. A drawback is that large volumes of purge water may be produced for large diameter or deep wells.

The **Low-Flow** method involves purging the well at a relatively low flow rate that minimizes drawdown, with the pump or tubing inlet located within the screened interval of the well. The well is sampled when water quality parameters are stable, adequately low turbidity is achieved, and the water level has achieved a stable drawdown (an unchanging water level). This method is often faster than Multiple-Volume Purge and generates less purge water. The method requires more skill and judgment on the part of the samplers.

The **Multiple-Volume Purge** method and the **Low-Flow** method can be considered equivalent for conventionally screened and filter-packed wells in that they both sample a flow-weighted average of water entering the well during pumping. However, other variables can result in differences between results with the two methods. In repeat sampling events, the sampling design should not change from one method to the other without appropriate cause. The transition should be noted in the report.

Minimum-Purge and **No-Purge** methods are based on the assumption that water within the screened interval of the well is at equilibrium with the water in the surrounding aquifer. This assumption should be carefully considered in the use of these methods and various cautions are discussed in sections below. The minimal-purge and no-purge methods are most useful for long-term monitoring and are generally inappropriate for the early stages of investigation. In some cases the methods might be used to gather screening-level data from wells that are too large to practically purge or have other sampling complications.

COPY

The **Minimum-Purge** and **No-Purge** methods collect water in the vicinity of the device under near-static conditions and are not equivalent to the multiple-volume purge and Low-Flow methods. Stratification of horizontal flow or vertical flow conditions within the well can result in non-intuitive and deceptive results. A comparison study should be conducted before transitioning a sampling program to the minimal-purge or no-purge methods.

3.2 Purging

Wells are purged to eliminate stagnant water residing in the casing and/or screen that has undergone geochemical changes or loss of VOCs. At the conclusion of purging, the desired flow-weighted average of water entering the well under pumping conditions will be available for sampling. Turbidity is often elevated during purging by the disturbance of formation materials at the borehole walls. As many contaminants (metals and many organics) will sorb to the formation particles, a sample including these particles will not represent the dissolved concentrations of the contaminants. Thus, a secondary goal of purging is to reduce the turbidity to the point that the sample will represent the dissolved concentration of contaminants.

In order to determine when a well has been adequately purged, field investigators should monitor, at a minimum, the pH, specific conductance and turbidity of the groundwater removed and the volume of water removed during purging. The measurements should be recorded in a purge table in the field logbook that includes the start time of purging, the parameter measurements at intervals during purging, estimated pumped volumes, depths to water for Low-Flow sampling, and any notes of unusual conditions. A typical purge table used for Low-Flow sampling is reproduced below.

3.3 Parameter Stabilization Criteria

With respect to the ground water chemistry, an adequate purge is achieved when the pH and specific conductance of the ground water have stabilized and the turbidity has either stabilized or is below 10 Nephelometric Turbidity Units (NTUs) (twice the Secondary Drinking Water Standard of 5 NTUs).

Stabilization occurs when, for at least three consecutive measurements, the pH remains constant within 0.1 Standard Unit (SU) and specific conductance varies no more than 5 percent. Other parameters, such as dissolved oxygen (DO) or oxidation-reduction potential (ORP), may also be used as a purge adequacy parameter. Normal stability goals for DO are 0.2 mg/L or 10% change in saturation, whichever is greater. DO and ORP measurements must be conducted using either a flow-through cell or an over-topping cell to minimize oxygenation of the sample during measurement. A reasonable ORP stability goal is a range of 20 mV, although ORP is rarely at equilibrium in environmental media and often will not demonstrate enough stability to be used as a purge stabilization parameter. Determining the frequency of measurements has generally been left to 'Best Professional Judgement'. Care is in order, as measurements recorded at frequent intervals with low flow rates can falsely indicate stability of parameters. Several measurements should be made early in the well purge to establish the direction and magnitude of trends, which can then inform the stability decision. Stability parameters should either be not trending, or approaching an asymptote, when a stability determination is made. As a matter of practice, parameter measurements are generally made at 5-10 minute intervals.

Because the measured groundwater temperature during purging is subject to changes related to surface ambient conditions and pumping rates, its usefulness is subject to question for the purpose of determining parameter stability. As such, it has been removed from SESD's list of parameters used for stability determination. Even though temperature is not used to determine stability, it is still advisable to record the temperature of purge water as it is often used in the interpretation of other parameters.

Information on conducting the stability parameter measurements is available in the SESD Operating Procedures for Field pH Measurement (SESDPROC-100), Field Specific Conductance Measurement (SESDPROC-101), Field Temperature Measurement (SESDPROC-102), Field Turbidity Measurement (SESDPROC-103), Field Measurement of Dissolved Oxygen (SESDPROC-106) and Field Measurement of Oxidation-Reduction Potential (SESDPROC-113).

Table 1, Purge and Sample Strategies with Equipment Considerations

Purging Strategy	Purge Eqpt	Sample Eqpt	Comments
Multi-Volume Purge	----------	----------	Overall Method Comments- Advantages: Consistent results can be achieved with minimal skill level required. Common, simple equipment can be used. Disadvantages: Can result in large volumes of purge water. Can take extended periods of time with large diameter wells or long water columns.
In this traditional method, 3-5 well volumes of water are removed from the top of the water column while verifying the stability of water quality parameters. Following the well purge, the well is sampled from the top of the water column.	Bailer	Bailer	Bailers are rarely used for purging due to the effort required, the difficulty of lowering turbidity adequately, and the possibility of aerating the upper water column.
	Electric Submersible Pump	Bailer	Common multiple-volume setup when depth to water exceeds 25 feet. Abbreviated pump decontamination procedure can be used between wells.
	Electric Submersible Pump	Electric Submersible Pump	Requires full pump decontamination and new tubing at each well. In most cases the pump would be deployed to the screened interval instead to perform Low-Flow sampling.
	Peristaltic Pump	Peristaltic Pump	Common, multi-volume setup when depth to water is less than 25 feet. Special sampling techniques are required for the collection of SVOCs and VOCs.
Low-Flow methods	----------	----------	Overall Method Comments- Advantages: Lower volumes of purge water. May be faster, especially with longer water columns. Disadvantages: Requires greater skill for consistent results. Higher tubing costs than multi-volume method.
The pump or tubing inlet is placed within the screened interval and the well is purged to stable water quality parameters while maintaining stable drawdown of the water level.	Electric Submersible Pump	Electric Submersible Pump	Commonly used when depth to water exceeds 25 feet. Pump is cleaned to sample equipment standards prior to sampling each well and new or dedicated tubing used for each well. Concerns have been raised concerning VOC loss from agitation in the turbine section or from sample heating.
	Peristaltic Pump	Peristaltic Pump	Commonly used where depth to water is less than 25 feet. Special sampling techniques required for the collection of SVOCs and VOCs. Concerns have been raised concerning VOC loss from vacuum created in sample tubing.
	Bladder Pump	Bladder Pump	Least danger of VOC loss as entire sample train is under positive pressure and little sample heating occurs. Difficult to remove large volumes of water in reasonable time. Mild surging effect may keep turbidity elevated in sensitive wells.
Minimum-Purge, No-Purge Methods	----------	----------	Overall Method Comments- Advantages: Very little or no waste water. Well suited to repeat sampling events. Likely faster with lower costs. Disadvantages: Not directly equivalent to other methods. Vertical stratification or vertical flow conditions in the screened interval can result in deceptive or non-intuitive analytical results.
Predicated on the assumption that aquifer flow through the well maintains the water in the screened interval in a state equivalent to that in the aquifer. This assumption should be proven or the data qualified. Sampling is conducted with little or no purge, or by equilibrating a sampler in screened interval.	Pumps, various	Pumps, various	In the minimum-purge method, the internal volume of the sample tubing and pump is calculated. One volume of the pump and tubing is purged to flush the equipment and the well is then sampled.
	na	Passive Diffusion Bags	In most common form, a sealed water-filled polyethylene bag is allowed to equilibrate in the water column. Suitable primarily for VOCs. Generally require 2 week minimum in-situ residence time.
	na	Hydrasleeves	Collect a fixed volume of water from a specific interval. Requires duplicate samplers or redeployment for larger volumes. Sorbtion issues may bias results.
	na	Snap sampler	Deploys a sample container in the sampling interval where it is allowed to equilibrate (commonly for two weeks) before being sealed insitu by the sampler mechanism and retrieved. Limited to specific containers.

COPY

3.4 Multiple-Volume Purge

In the traditional Multiple-Volume Purge method, water is removed from the top of the water column, causing water to enter the screen and flush stagnant casing water upward to be subsequently removed. In recognition of the mixing of fresh and stagnant water in the casing section, a minimum of three well volumes is removed, at which time purging can be terminated upon parameter stabilization. Wells can be assumed to be adequately purged when five well volumes have been removed, although further purging may be conducted to meet specific goals, such as further reduction of turbidity.

3.4.1 Purge Volume Determination

Prior to initiating the purge, the amount of water standing in the water column (water inside the well riser and screen) should be determined The diameter of the well is determined and the water level and total depth of the well measured and recorded prior to inserting a pump or tubing into the well. The water level is subtracted from the total depth, providing the length of the water column. Specific methodology for obtaining these measurements is found in SESD Operating Procedure for Groundwater Level and Well Depth Measurement (SESDPROC-105).

Once this information is obtained, the volume of water to be purged can be determined using one of several methods. The well volume can be calculated using the equation:

$$V = 0.041\ d^2h$$

Where:
h = length of water column in feet
d = diameter of well in inches
V = one well volume in gallons

Alternatively, the volume of standing water in the well and the volume of three water columns may be determined using a casing volume per foot factor for the appropriate diameter well, such as *Table 2 Well Casing Diameter Volume Factors*. The water column length is multiplied by the appropriate factor in the Table 2 to determine the single well volume, three well volumes, or five well volumes for the well in question. Other acceptable methods include the use of nomographs or other equations or formulae.

36	52.9	159	264
48	94.0	282	470

*** See text for discussion on terminating purge at five well volumes**

An adequate purge is normally achieved when three to five well volumes have been removed. The field notes should reflect the single well volume calculations or determinations, according to one of the above methods, and a reference to the appropriate multiplication of that volume, i.e., a minimum three well volumes, clearly identified as an initial purge volume goal.

COPY

3.4.2 Pumping Conditions

The pump or tubing inlet should be located at the top of the water column. If the pump is placed deep into the water column, the water above the pump may not be removed, and the subsequent samples, particularly if collected with a bailer, may not be representative of the aquifer conditions. If the recovery rate of the well is faster than the pump rate and no observable draw down occurs, the pump should be raised until the intake is as close as possible to the top of the water column for the duration of purging. If the pump rate exceeds the recovery rate of the well, the pump or tubing will have to be lowered to accommodate the drawdown.

3.4.3 Stability of Chemical Parameters

In the multiple-volume purge method, a stability determination may be made after three well volumes have been removed. If the chemical parameters have not stabilized according to the above criteria, additional well volumes (up to a total of five well volumes) should be removed. If the parameters have not stabilized after the removal of five well volumes, it is at the discretion of the project leader whether or not to collect a sample or to continue purging. If, after five well volumes, pH and conductivity have stabilized and the turbidity is still decreasing and approaching an acceptable level, additional purging should be considered to obtain the best sample possible.

3.4.4 Sample Collection

There are several means by which sampling can proceed after adequate volume has been purged and water quality parameters have stabilized. If a submersible pump and tubing are of suitable material and cleanliness for sample collection, sampling can proceed immediately by directly filling bottles from the tubing outlet. Commonly with the multiple-volume purge method, the pump is set up and cleaned in a manner suitable only for purging. In these cases, the pump is stopped and removed from the well and sampling proceeds with a bailer per the procedure described in Section 3.6.3. The pump should have a check valve to prevent water in the pump tubing from discharging back into the well when the pump is stopped. If a peristaltic pump is used, sampling can proceed as described in Section 3.6.1.

3.5 Low-Flow Method

This method involves placing the pump or tubing inlet within the screened interval of the well and purging at a low enough rate to achieve stable drawdown and minimal depression of the water level. The well is sampled without interruption after field parameters are stable and low turbidity is achieved. In general, only water in the screened interval of the well is pumped and the stagnant water in the well casing above the screen is not removed. Wells can generally be sampled in less time with less purge volume than with the multi-volume purge method. More attention is required in the assessment of stability criteria than the multi-volume method.

COPY

3.5.1 Nomenclature

A variety of terminology has been used to describe this method by SESD and others, including: 'low flow', 'low-flow/low-volume', 'tubing-in-screen method', 'low flow/ minimal drawdown', and 'micropurge'. The current preferred SESD terminology for this method is 'Low-Flow'. As the term 'micropurge' is sometimes used to refer to minimal-purge methods and has been trademarked by a vendor, the use of 'micropurge' to describe the Low-Flow method generally introduces ambiguity and confusion and thus the use of the term is discouraged.

3.5.2 Placement of Pump Tubing or Intake

The inlet of the pump tubing or intake of the submersible pump is placed in the approximate mid-portion of the screened interval of the well. While it is often thought that particular aquifer zones can be targeted by specific pump or intake placement, for conventionally constructed screened and filter-packed monitoring wells the zone monitored is only weakly dependent on the intake placement (Varljen, Barcelona, Obereiner & Kaminski, 2006).

The pump or tubing can be placed by carefully lowering them to the bottom of the well and then withdrawing half of the screen length, plus the length of any sump sections at the bottom of the well. A drawback of this approach is that it may stir up sediment at the well bottom. An alternate approach is to lower the pump or tubing a measured distance to place it at mid-screen without touching the bottom of the well. In the case of pumps, special care should be used in lowering them slowly, especially in the screened interval, to prevent elevating turbidity needlessly by the surging action of the pump.

3.5.3 Conditions of Pumping

Prior to initiation of pumping, a properly decontaminated well sounder should be lowered into the well to measure the water level prior to and during the purging process. Ideally, there should be only a slight and stable drawdown of the water column after pumping begins. In some cases, it will be necessary for the well to drawdown a considerable distance (10 ft or more in extreme cases) to maintain a minimal usable pumping rate for sampling (100-200 ml/min). Excessive pump rates and drawdown can result in increased turbidity, or aeration of the sample if the screen is exposed. Stable drawdown is an essential condition of the Low-Flow method. If the stable drawdown condition cannot be met, then one of the other methods should be employed.

3.5.4 Stability of Chemical Parameters

As with the Multiple-Volume Purging method described, it is important that all chemical parameters be stable prior to sampling. It is common for wells to require the removal of one of more screened-interval volumes (~2 gal for a 10 ft screen in a 2" dia. well) to achieve stability. Although it is possible for wells to achieve stability with lower purge volumes, the sampler should exercise caution in making an early stability determination.

COPY

3.5.5 Sample Collection

Low-Flow sampling is implemented using a pump and tubing suitable for sampling. After making the determination of parameter stability with stable drawdown, sampling can proceed immediately. Where submersible or bladder pumps are used, sampling can proceed by directly filling bottles from the tubing outlet. Where peristaltic pumps are used, sampling can proceed per the procedure described in Section 3.6.3.

3.6 Minimum-Purge and No-Purge Sampling

The Minimum-Purge and No-Purge sampling methods are employed when it is necessary to keep purge volumes to an absolute minimum, where it is desirable to reduce long-term monitoring costs, or where large wells or other limitations prevent well purging. The underlying assumption when employing these methods is that the water within the well screen is equilibrated with the groundwater in the associated formation. This assumption should be demonstrated prior to use of these methods or the results suitably qualified. These methods are generally impractical for SESD to implement because of the common lack of hydrogeological information in early investigative phases and the necessity with some methods that the samplers be pre-deployed to allow equilibration.

Vertical flow conditions and stratification of the water column have also been known to result in deceptive and non-intuitive analytical results. The use of these methods in the early phases of investigation can easily result in misinterpretation of site conditions and plume boundaries.

Particular caution is in order in the use of these methods when any of the following conditions exist:

- Low hydraulic conductivity ($K<10^{-5}$ cm/sec)
- Low groundwater surface gradients
- Fractured bedrock
- Wells with long screened intervals
- Wells screened in materials of varying hydraulic conductivities

If it is desired to transition a long-term monitoring program to Minimum-Purge or No-Purge sampling, a pilot study should be conducted where the Minimum-Purge or No-Purge sample results are compared to the conventional methods in use. Multiple samplers may be deployed in the screened interval to help establish appropriate monitoring intervals.

These methods are in common use and for the purposes of the SESD quality system they can be considered standard, but unaccredited, procedures. Several Minimum-Purge or No-Purge procedures that might be employed are shown below. It is not the intention to recommend particular equipment or vendors, and other equipment that can accomplish the same goals may be suitable.

COPY

3.6.1 Minimum Purge Sampling

The pump or tubing inlet is deployed in the screened interval. A volume of water equal to the internal pump and tubing volume is pumped to flush the equipment. Sampling then proceeds immediately. While superficially similar to Low-Flow sampling, the results obtained in this method will be sensitive to the vertical pump or tubing inlet placement and are subject to the limitations described above.

3.6.2 Passive Diffusion Bags

The no-purge Passive Diffusion Bag (PDB) typically consists of a sealed low-density polyethylene (LDPE) bag containing deionized water. They are deployed in the screened interval of a well and allowed to equilibrate, commonly for two weeks, prior to retrieval and decanting of the water into sample containers. Many volatile organic compounds will reach equilibrium across the LDPE material, including BTEX compounds and many chlorinated solvents. Compounds showing poor equilibration across LDPE include acetone, MTBE, MIBK, and styrene. PDBs have been constructed of other materials for sampling other analytes, but the vast majority of PDB samplers are of the LDPE material. Various vendors and the Interstate Technology and Regulatory Council (ITRC) can provide additional information on these devices.

3.6.3 HydraSleevesTM

HydraSleeeves™ are no-purge grab sampling devices consisting of a closed-bottom sleeve of low-density polyethylene with a reed valve at the top. They are deployed in a collapsed state to the desired interval and fill themselves through the reed valve when pulled upward through the sampling interval. The following is a summary of their operation:

Sampler placement – A reusable weight is attached to the bottom of the sampler or the sampler is clipped to a weighted line. The HydraSleeve™ is lowered on the weighted line and placed with the top of the sampler at the bottom of the desired sampling interval. In-situ water pressure keeps the reed valve closed, preventing water from entering the sampler. The well is allowed to return to equilibrium.

Sample collection - The reed valve opens to allow filling when the sampler is moved upward faster than 1 foot per second, either in one continuous upward pull or by cycling the sampler up and down to sample a shorter interval. There is no change in water level and only minimal agitation during collection.

Sample retrieval - When the flexible sleeve is full, the reed valve closes and the sampler can be recovered without entry of extraneous overlying fluids. Samples are removed by puncturing the sleeve with the pointed discharge tube and draining the contents into containers for sampling or field parameter measurements.

COPY

Because the HydraSleeve™ is retrieved before equilibration can occur and they are constructed of non-Teflon® materials, there may be issues with sorbtion of contaminants in the use of this sampler.

3.6.4 Snap Samplers

The Snap Sampler is a patented no-purge groundwater sampling device that employs a double-end-opening bottle with "Snap" sealing end caps. The dedicated, device is deployed at the desired position in the screened interval with up to six Snap Samplers and six individual sampling bottles. The device is allowed to equilibrate in the screened interval and retrieved between 3 and 14 days after deployment. Longer deployments are possible to accommodate sampling schedules.

To operate, Snap Samplers are loaded with Snap Sampler bottles and the "Snap" caps are set into an open position. Samplers are deployed downhole with an attachment/trigger line and left to equilibrate downhole. To collect samples, the Snap Sampler bottles seal under the water surface by pulling a mechanical trigger line, or using an electric or pneumatic trigger system. The trigger releases Teflon® "Snap Caps" that seal the double-ended bottles. The end caps are designed to seal the water sample within the bottles with no headspace vapor. After the closed vial is retrieved from the well, the bottles are prepared with standard septa screw caps and labeled for laboratory submittal.

The manufacturer of the Snap Sampler provides considerable additional information on the validation and use of the device.

3.7 Equipment Considerations

Equipment choices are dictated by the purging and sampling method used, the depth to water, the quantity of water to be pumped, and quality considerations. The advantages and disadvantages of various commonly used pumps are discussed in the sections below and summarized in *Table 1, Purge and Sample Strategies with Equipment Considerations.* Additional information on the use of individual pumps is available in SESD Operating Procedure for Pump Operation, SESDPROC-203.

3.7.1 Use of Peristaltic Pumps

Peristaltic pumps are simple, inexpensive, and reliable equipment for purging and sampling where the limit of suction is not exceeded (approximately 25-30 vertical feet from the groundwater surface to the pump). When used for sampling, they should be equipped with new Teflon® tubing for each well. The flexible peristaltic pump-head tubing should also be changed between wells.

Samples for organic analyses cannot be exposed to the flexible peristaltic pump-head tubing, both due to the risk that the tubing would sorb contaminants and the propensity of this tubing to contribute organic compounds to the sample. Samples can be collected without contact with the pump-head tubing by the use of vacuum transfer caps for

COPY

analyses requiring 1 liter glass containers and the use of the 'soda-straw' method for the filling of VOC vials.

The sample containers for the more turbidity-sensitive analyses are filled first, as filling the VOC vials (and to a lesser extent the glass bottles) may disturb the well and increase turbidity. The most appropriate order of sampling with a peristaltic pump is generally to fill poly containers for metals and classical analyses, followed by glass bottles for SVOCs and associated analyses, and finally to fill 40 ml VOC vials.

The following step-by-step procedure assumes that the pump has been set up per SESD Operating Procedure for Pump Operation (SESDPROC-203) and that containers for a typical full suite of analyses will be filled. The procedure is suitable for use with either multi-volume Purge and Low-Flow methods with minor differences in the collection of VOCs:

1. Deploy the lower end of the tubing to the desired point in the well. This would be the top-of-water for the multi-volume purge method or to the mid-screen for the Low-Flow method. Connect the well tubing to the flexible pump-head tubing and connect a short piece of tubing from the pump-head tubing to a measuring bucket.

2. Turn on the pump and establish a suitable pumping rate. For the multi-volume purge method, the rate will generally be a relatively fast rate that the well will sustain without elevating turbidity. For the low-flow method the pump rate is established at a slower rate to maintain a minimal and stable drawdown level.

3. Proceed with the measurement of water quality parameters and adjust the pump rate as needed to achieve low turbidity and stable drawdown.

4. When the well purge has been determined to be sufficient, fill containers for metals and classical analyses directly from the pump outlet. There is no need to interrupt pumping. The tubing should be held at the opening of the container and should not touch the container during filling. Protect caps from dust and debris during filling.

5. After filling the containers for metals and classical analyses stop the pump. Make sure that the tubing leading into the well is secured against movement during the following operations.

6. Create a crimp in the well tubing approximately one foot from the pump and grasp the crimped tubing in one hand. It is generally most effective to create a double 'Z' crimp.

7. Cut the sample tubing between the crimp and the pump. The tightly-held crimped tubing should keep water from running back into the well. In lieu of

COPY

cutting the tubing, the well tubing can be disconnected from the pump and a short piece of tubing connected in its place.

8. Insert both free ends of the tubing into the ferrule-nut fittings of a pre-cleaned Teflon® transfer cap assembly and tighten the nuts. Attach the transfer cap assembly to the first glass container for semi-volatile analysis and securely tighten the threaded ring.

9. Turn the pump on. Very slowly release the 'Z' crimp in the sample tubing. As vacuum builds up in the sample container, water should begin to move up the sample tubing instead of back into the well. If after several minutes water has not begun moving up the tubing, check the tightness of fittings and the attachment of the cap to the bottle. Allowing water to rush back down the tubing from the 'Z' crimp can surge the well and elevate turbidity.

10. Fill the container to about halfway between the shoulder and the neck. Crimp the well tubing. Move the transfer cap to any additional bottles and repeat the filling process.

11. When finished filling bottles with the transfer cap, again crimp the tubing. Remove the well tubing from the transfer cap and reattach it to the pump. Slowly run the pump and release the crimp until water is approaching the flexible peristaltic tubing.

12. Make a kink or otherwise mark the tubing at the top of the casing in case the tubing needs to be reinserted for additional sample volume. Slowly remove the tubing from the well and coil it in one hand in loose coils. With the top end of the tubing blocked, water is retained in the tubing as it is withdrawn, much as in a capped soda straw, hence the name for this method.

13. Remove the top from a 40 ml VOC vial and position the end of the sample tubing near the top of the vial. Reverse the pump direction and turn the speed knob to its slowest position. Turn on the pump and slowly increase speed until water slowly fills the vial. Fill the vial with a slow laminar flow that does not agitate the water in the vial or entrain bubbles. Continue to fill the vial until a convex meniscus forms on the top of the vial and turn off the pump.

14. Carefully screw the septum-lid to the vial and fasten firmly. Invert the vial and tap on your knuckles to check for bubbles. Carefully add additional volume to the vial if necessary. Small bubbles are undesirable but may be unavoidable with some media, especially when using pre-preserved vials.

15. Repeat the filling process for additional vials. Avoid partially filling vials as the available water in the tubing is used. If more volume is required than that contained in the tubing, purge the remaining water from the tubing and reinsert

COPY

the tubing in the well to the level marked previously. Run the pump to refill the tubing. If performing Low-Flow sampling, run additional volume through the pump to purge any water that may have been collected from the stagnant water column.

16. Fill additional vials as needed. Be sure that any water that has contacted the flexible peristaltic tubing is not pumped into a vial.

3.7.2 Use of Submersible Centrifugal Pumps

Submersible centrifugal pumps are used in wells of 2" diameter and larger. They are especially useful where large volumes of water are to be removed or when the groundwater surface is a large distance below ground surface. Commonly used pumps are the Grundfos® Redi-Flo2, the Geotech GeoSub, and the various 'Monsoon' style pumps. Other pumps are acceptable if constructed of suitable materials.

When used with the Multiple-Volume Purge method, the pump is generally used only to purge, with sampling performed with a bailer. In this use, the pump can be used with polyethylene or other tubing or hose that will not contribute contaminants to the well. The pump and tubing is decontaminated between wells per the relevant provisions of SESD Operating Procedure for Field Equipment Cleaning and Decontamination (SESDPROC-205). When used in this application the pump should be equipped with a check valve to prevent water in the discharge tubing or hose from running back down into the well.

When used for Low-Flow purging and sampling the pump must be constructed of stainless steel and Teflon®. Pump cleaning at each well follows the more stringent procedures described in SESD Operating Procedure for Field Equipment Cleaning and Decontamination SESDPROC-205) for this application. The sample tubing should be either new Teflon® tubing, or tubing dedicated to each well. Dedicated tubing would ideally be cleaned between uses, but tubing stored in the well casing between uses is acceptable, although caution should be exercised where very high concentrations of contaminants have been sampled in a well.

3.7.3 Use of Bailers

Bailers are a common means of sampling when the Multiple-Volume Purge method is used. They are occasionally used for purging when other equipment is not available or has failed. As bailers surge the well on each withdrawal, it is very difficult to lower turbidity adequately during a well purge, and when used for sampling they can elevate turbidity in a well before all sample volume is collected. If not lowered carefully into the top of the water column, the agitation may strip volatile compounds. Due to the difficulties and limitations inherent in their use, other sampling or purging means should generally be given preference.

COPY

Bailers should be closed-top Teflon® bailers with Teflon® coated stainless steel leaders used with new nylon haul rope. They are lowered gently into the top of the water column, allowed to fill, and removed slowly. It is critical that bailers be slowly and gently immersed into the top of the water column, particularly during final stages of purging and during sampling, to minimize turbidity and loss of volatile organic constituents.

If the well has previously been purged with a pump, there is likely stagnant water at the top of the well that was above the pump or tubing inlet. Several bailers of water should be retrieved and discarded to assure the upper stagnant water has been removed.

When sampling, containers are filled directly by pouring from the outlet at the top of the bailer. Containers for metals analysis should be filled first in case the bailing process increases well turbidity. VOC vials should be filled carefully and slowly with a laminar flow to reduce agitation and the stripping of VOCs.

3.7.4 Use of Bladder Pumps

Bladder pumps use a source of compressed gas to compress and release a bladder straddled by check valves within the pump body. As the bladder is compressed, water is expelled out the upper check valve to the surface. When gas pressure is released, the bladder refills as well water enters the lower pump inlet. A control unit is used to control the pressure and timing of the bladder inflation gas flow.

Bladder pumps are capable of pumping from moderate depths to water, but are not capable of high flow rates. As they operate cyclically, the well is surged slightly on each cycle and it may be difficult to lower turbidity in sensitive or poorly developed wells. As the entire sample train is under positive pressure and the pumps develop little heat, they are ideal for sampling VOCs.

Prior to sampling and between each well the pumps are cleaned internally and externally per the provisions of SESD Operating Procedure for Field Decontamination (SESDPROC-205) and a new Teflon® bladder installed. New (or dedicated) Teflon® sample tubing is used at each well, although polyethylene tubing can be used for the compressed gas drive line and cleaned between each well.

3.7.5 Use of Inertial Pumps

Inertial pumps consist of a check valve which is affixed to the lower end of semi-rigid tubing. The tubing and valve are cycled up and down, allowing water to alternately be drawn into the check valve inlet and then pulled up towards the surface. Two commonly used inertial pumps are the Waterrra® pump for wells larger than 1" and the Geoprobe® Tubing Check Valve for small diameter wells. The primary use of these pumps is in well development where their near-immunity to silt is an advantage. Inertial pumps should not be used for the final well purge or for sampling as there is a low likelihood of

COPY

reducing turbidity to appropriate levels and they have the potential to strip volatiles from the water column through agitation.

To set up the pump, the check valve is screwed onto the discharge tubing where it will cut its own threads. In the case of the Waterra® pump, a surge block can also be pressed onto the check valve. The pump is lowered into the well to the screened interval and rapidly cycled up and down a distance of 3" -12". The stroke length and speed are adjusted for pumping effect. Electric actuators can be used to reduce the effort involved. The pump should be moved to different levels in the screen to surge the entire screen. The pump can occasionally be lowered to the bottom of the well to vacuum out silt. Any silt that clogs the valve is usually quickly rinsed out by the pump cycling and if the clog remains the pump is easily retrieved and redeployed.

The surging activity is usually continued until turbidity is lowered to a measurable range and cannot easily be lowered further. Further development or purging is then conducted with other pumps.

3.8 Wells With In-Place Plumbing

Wells with in-place plumbing are commonly found at municipal water treatment plants, industrial water supplies, private residences, and in other applications. Many permanent monitoring wells at active facilities are also equipped with dedicated, in-place pumps.

A permanent monitoring well with an in-place pump may be treated as other monitoring wells without pumps. Since the in-place pump is generally "hard" mounted at a pre-selected depth, it cannot be moved up or down during purging and sampling. If the pump inlet is above the screened interval, the well should be sampled using the Multiple-Volume Purge method. If the pump intake is located within the screened interval, the well can be sampled using Low-Flow procedures. Known details of pump type and construction, tubing types, pump setting depths, and any other available information about the system should be recorded in the field logbook.

In the case of the other types of wells, e.g., municipal, industrial and residential supply wells, there is typically not enough known about the construction aspects of the wells to apply the same criteria as used for monitoring wells. The volume to be purged in these situations therefore depends on several factors: whether the pumps are running continuously or intermittently and whether or not any storage/pressure tanks are located between the sampling point and the pump. The following considerations and procedures should be followed when purging wells with in-place plumbing under the conditions described.

3.8.1 Continuously Running Pumps

If the pump runs more or less continuously, no purge (other than opening a valve and allowing it to flush for a few minutes) is necessary. If a storage tank is present, a spigot,

COPY

valve or other sampling point should be found located between the pump and the storage tank. If no valve is present, locate and use the valve closest to the tank. Measurements of field parameters are recorded immediately prior to the time of sampling.

3.8.2 Intermittently or Infrequently Running Pumps

If the pump runs intermittently or infrequently, best judgment should be utilized to remove enough water from the plumbing to flush standing water from the piping and any storage tanks that might be present. Often under these conditions, 15 to 30 minutes of purging will be adequate. Measurements of pH, specific conductance, temperature and turbidity should be made and recorded at intervals during the purge and the final measurements made at the time of sampling should be considered the measurements of record for the event.

3.9 Temporary Monitoring Wells

3.9.1 General Considerations

As temporary wells are installed for immediate sample acquisition, the procedures used to purge temporary ground water monitoring wells may differ from those for permanent wells. Temporary wells include standard well screen and riser placed in boreholes created by hand augering or drilling, or they may consist of a drive rod and screen such as a direct-push Geoprobe® Screen Point that is driven into place at the desired sampling interval. As aquifer water enters the sampler immediately upon deployment, the requirement to remove several volumes of water to replace stagnant water does not necessarily apply. In practice, developing and purging the well to usable turbidity levels will remove many times the water that would be removed in a Multiple-Volume Purge with calculated well volumes. It is important to note, however, that the longer a temporary well is in place and not sampled, the more stagnant the water column becomes and the more appropriate it becomes to apply standard permanent monitoring well purging criteria to achieve representative aquifer conditions in the sample.

3.9.2 Development of Temporary Wells

In cases where the temporary well is to be sampled immediately after installation, purging is conducted primarily to mitigate the impacts of installation. In most cases, temporary well installation procedures disturb the existing aquifer conditions, causing extreme turbidity. The goal of purging is to reduce the turbidity and remove the volume of water in the area directly impacted by the installation procedure.

The following procedure has been found to be effective in developing and sampling small diameter temporary wells where a peristaltic pump can be used. Turbidity can generally be lowered to 50 NTU at the time of sampling and turbidity less than 10 NTU is often achieved.

COPY

1. Cut peristaltic tubing to reach to the bottom of the well. Connect to a peristaltic pump and begin pumping at a high rate.

2. Use the tubing to vacuum out sediment at the bottom of the well.

3. Aggressively surge the end of the tubing in the screened interval by cycling the tubing rapidly up and down. Periodically repeat vacuuming of the well bottom.

4. When a visible 'break' to a lower turbidity is observed, cease surging the well and begin lowering the pumping rate.

5. When the water clears (turbidity < 100-200 NTU) begin raising the end of the tubing to the top of the water column.

6. Continue purging from the top of the water column, lowering the pump speed as required to lower turbidity. When adequately low turbidity and stable water quality parameters have been achieved, sampling can proceed.

Where the water level is below the limit of suction in a small diameter temporary well, a Geoprobe® mechanical bladder pump can be used for purging and sampling. The well should first be developed with an inertial pump to remove the bulk of silt and suspended particles that could clog the check valves of the bladder pump. The inertial pump is used to vacuum out the bottom of the well and surged in the screened interval until a 'break' to lower turbidity is observed prior to deployment of the bladder pump. Since the mechanical bladder pump requires cumbersome redeployment to change its pumping level, it should be deployed low enough in the water column that the water level will not be lowered below the pump during purging and sampling. The mechanical bladder pump is generally deployed above the screened interval to facilitate the settling of particles, but below the top of the water column to alleviate the need to reset the pump. Detailed instructions on the deployment of the pump can be found in SESDPROC203, Pump Operation.

3.9.3 Decommissioning of Temporary Wells

After temporary wells have fulfilled their purpose, they should be properly decommissioned similar to permanent wells. In general, the casings and screens can be easily removed and the borehole should then be pressure grouted from the bottom of the original borehole to prevent surface contamination of the aquifer, cross-connection of aquifers, and to remove a potential vapor pathway.

Direct-push screen-point wells may be decommissioned by one of two methods.

1. A disposable screen is used. The sampling sheath is pulled off of the screen and a 30% solids bentonite grout is pumped down the tool string as the rods are withdrawn.

COPY

Grout volumes are measured during pumping to assure that the hole is completely filled. The disposable screen is left behind at the bottom of the borehole.

2. The screen is removed with the sampler sheath and tool string. The hole is immediately re-entered with an empty sample sheath with disposable point. Upon reaching the original total depth of the temporary well, 30% solids bentonite grout is pumped down the tool string with the pumped volume monitored during tool string withdrawal to assure that the hole is completely filled.

A system is available to insert a small diameter grouting tube down through the screen-point screen. Grout is pumped through the grouting tube while the tools are withdrawn. SESD does not use this system as grout denser than 20% solids cannot reliably be installed with this system.

Additional guidance on decommissioning may be found in SESDGUID-101, Design and Installation of Monitoring Wells.

3.9.4 Other Considerations for Direct-Push Groundwater Sampling

With certain direct push sampling techniques, such as the Hydropunch™ and other discrete samplers used with cone-penetrometer rigs, purging is either not practical or not possible. The sampling device is simply pushed or driven to the desired depth and opened, whereupon the sample is collected and retrieved. As a result, some samples collected in this way may not be satisfactory or acceptable for certain analyses, i.e., the sampler may collect a turbid sample inappropriate for metals analyses or the sample may have inadequate volume to achieve desired reporting levels.

3.10 Wells Purged to Dryness

In some situations, even with slow purge rates, a well may be purged dry in the Multiple-Volume Purge method or stable drawdown cannot be maintained in the Low-Flow method. In these cases, the well should be purged to dryness (evacuated) and sampled upon recovery of adequate volume for sampling. Sampling should occur as soon as adequate volume has recovered. The field parameters should be measured and recorded at the time of sample collection as the measurements of record for the sampling event.

Sampling under these conditions is not ideal and suitable qualifications of the data should be included in the report. Water cascading down the screen into the well may strip volatile compounds and elevate turbidity. Although suffering from other limitations, No-Purge methods may prove useful for these wells.

COPY

4 Additional Purging and Sampling Considerations

4.1 Field Care of Purging Equipment

New plastic sheeting should be placed on the ground surface around the well casing to prevent contamination of the pumps, hoses, ropes, etc., in the event they accidentally come into contact with the ground surface or, for some reason, they need to be placed on the ground during the purging event. It is preferable that hoses used in purging that come into contact with the ground water be kept on a spool or contained in a large wash tub lined with plastic sheeting, both during transportation and during field use, to further minimize contamination by the transporting vehicle or the ground surface.

Careful consideration shall be given to using submersible centrifugal or bladder pumps to purge wells which are excessively contaminated with oily compounds as it may be difficult to adequately decontaminate severely contaminated pumps under field conditions. When wells of this type are encountered, alternative equipment, such as bailers or peristaltic pumps, should be considered.

4.2 Investigation Derived Waste

Purging and field cleaning of equipment generates liquid investigation derived waste (IDW), the disposition of which must be considered. See SESD Operating Procedure for Management of Investigation Derived Waste (SESDPROC-202) for guidance on management or disposal of this waste.

4.3 Sample Preservation

After sample collection, all samples requiring preservation must be preserved as soon as practical. Consult the Analytical Services Branch Laboratory Operations and Quality Assurance Manual (ASBLOQAM) for the correct preservative for the particular analytes of interest. All samples preserved using a pH adjustment (except VOCs) must be checked, using pH strips, to ensure that they were adequately preserved. This is done by pouring a small volume of sample over the strip. Do not place the strip in the sample. Samples requiring reduced temperature storage should be placed on ice immediately.

4.4 Special Sample Collection Procedures

4.4.1 Trace Organic Compounds and Metals

Special sample handling procedures should be instituted when trace contaminant samples are being collected. All sampling equipment, including pumps, bailers, water level measurement equipment, etc., which contacts the water in the well must be cleaned in accordance with the cleaning procedures described in the SESD Operating Procedure for Field Equipment Cleaning and Decontamination (SESDPROC-205) or SESD Operating Procedure for Field Equipment Cleaning and Decontamination at the FEC (SESDPROC-

COPY

206). Pumps should not be used for sampling unless the interior and exterior portions of the pump and the discharge hoses are thoroughly cleaned. Rinse blank samples should be collected to verify the adequacy of cleaning when using a sampling pump other than a peristaltic pump.

4.4.2 Order of Sampling with Respect to Analytes

In many situations when sampling permanent or temporary monitoring wells, sufficiently low turbidity is difficult to achieve and maintain. Removal and insertion of equipment after the purge or during sampling may negate the low turbidities achieved during purging and elevate turbidity back to unacceptable levels. For this reason, it is important that special efforts be used to minimize any disturbance of the water column after purging and to fill sample containers for metals analysis first. The preferred order of sampling is metals first, followed by other inorganic analytes, extractable organic compounds, and finally volatile organic compounds.

4.5 Filtering

As many contaminants are known to sorb to soil particles, the normal goal of sampling is to reduce the presence of these particles (measured by turbidity) in order that the dissolved concentration of contaminants can be obtained. However, transport of sorbed contamination on colloidal particles can be a means of contaminant transport on some sites. For this reason, the SESD approach is to reduce turbidity through the careful purging of wells, rather than through filtering of samples, in order that the colloidal particles would be included in the sample.

As a standard practice, ground water samples will not be filtered for routine analysis. Filtering will usually only be performed to determine the fraction of major ions and trace metals passing the filter and used for flow system analysis and for the purpose of geochemical speciation modeling. Filtration is not acceptable to correct for improperly designed or constructed monitoring wells, inadequate well development, inappropriate sampling methods, or poor sampling technique.

When samples are collected for routine analyses and are filtered, both filtered and non-filtered samples will be submitted for analyses. Samples for organic compounds analysis should not be filtered. Prior to filtration of the ground water sample for any reason other than geochemical speciation modeling, the following criteria must be demonstrated to justify the use of filtered samples for inorganic analysis:

1. The monitoring wells, whether temporary or permanent, have been constructed and developed in accordance with the SESD Guidance Document, Design and Installation of Monitoring Wells (SESDGUID-001).

2. The ground water samples were collected using sampling techniques in accordance with this section, and the ground water samples were analyzed in accordance with USEPA approved methods.

COPY

3. Efforts have been undertaken to minimize any persistent sample turbidity problems. These efforts may consist of the redevelopment or re-installation of permanent ground water monitoring wells or the implementation of carefully conducted low flow rate sampling techniques.

If filtration is necessary for purposes of geochemical modeling or other **pre-approved** cases, the following procedures are suggested:

1. Accomplish in-line filtration through the use of disposable, high capacity filter cartridges (barrel-type) or membrane filters in an in-line filter apparatus. The high capacity, barrel-type filter is preferred due to the higher surface area associated with this configuration. If a membrane filter is utilized, a minimum diameter of 142 mm is suggested.

2. When using pumps for sampling, the filter can generally be attached directly to the pump outlet. When sampling with a bailer or when otherwise required, an initial unfiltered sample with extra volume will be collected, and a peristaltic pump with filter used to decant and filter the sample to the final sample container.

3. Use a 0.45 µm pore-size filter to remove most non-dissolved particles. A 5 µm or 10 µm pore-size filter should be used for the purpose of determining colloidal constituent concentrations.

4. Fill the filter and rinse with approximately one additional filter volume prior to filling sample bottles

Potential differences can result from variations in filtration procedures used to process water samples for the determination of trace element concentrations. A number of factors associated with filtration can substantially alter "dissolved" trace element concentrations; these include filter pore size, filter type, filter diameter, filtration method, volume of sample processed, suspended sediment concentration, suspended sediment grain-size distribution, concentration of colloids and colloidally-associated trace elements, and concentration of organic matter. Therefore, consistency is critical in the comparison of short-term and long-term results. Further guidance on filtration may be obtained from the following: 1) Metals in Ground Water: Sampling Artifacts and Reproducibility; 2) Filtration of Ground Water Samples for Metals Analysis; and 3) Ground Water Sampling - A Workshop Summary. See Section 1.4, References, for complete citation for these documents.

4.6 Bacterial Sampling

Whenever wells (normally potable wells) are sampled for bacteriological parameters, care must be taken to ensure the sterility of all sampling equipment and all other equipment entering the well. Further information regarding bacteriological sampling is available in the following: 1) Sampling for Organic Chemicals and Microorganisms in

COPY

the Subsurface; 2) Handbook for Evaluating Water Bacteriological Laboratories; and 3) Microbiological Methods for Monitoring the Environment, Water and Wastes. See Section 1.4, References, for complete citation for these documents.

4.7 Specific Sampling Equipment Quality Assurance Techniques

All equipment used to collect ground water samples shall be cleaned as outlined in the SESD Operating Procedure for Field Equipment Cleaning and Decontamination (SESDPROC-205) or SESD Operating Procedure for Field Equipment Cleaning and Decontamination at the FEC (SESDPROC-206). Malfunctioning equipment should be labeled in the field and repaired, before being stored at the conclusion of field studies. Cleaning procedures utilized in the field or field repairs shall be thoroughly documented in field records.

4.8 Auxiliary Data Collection

During ground water sample collection, it is important to record a variety of ground water related data. Included in the category of auxiliary data are water levels measured according to the SESD Operating Procedure for Groundwater Level and Well Depth Measurement (SESDPROC-105), well volume determinations, pumping rates during purging, and, driller or boring logs. This information should be documented in the field records.

4.9 Well Development

Wells may be encountered that are difficult to sample effectively due to inadequate initial development or the need for redevelopment due to scaling, sedimentation, corrosion, or biofouling. These wells may produce water only at low flow rates or water with chronically elevated turbidity. Redevelopment of these wells should be considered as the process can improve sample quality and speed field operations. Well development procedures are described in Design and Installation of Monitoring Wells (SESDGUID-101).

EXHIBIT P-3

FIELD INDICATOR PARAMETER MEASUREMENT PROCEDURES

Region 4 U.S. Environmental Protection Agency Laboratory Services and Applied Science Division Athens, Georgia	
Operating Procedure	
Title: Field pH Measurement	ID: LSASDPROC-100-R5
Issuing Authority: LSASD Field Branch Chief	
Review Issue Date: July 23, 2020	Review Due Date: July 23, 2024

Purpose

This document describes procedures, methods and considerations to be used and observed when conducting field pH measurements in aqueous phase environmental media, including groundwater, surface water and certain wastewaters.

Scope/Application

The procedures contained in this document are to be used by field personnel when measuring the pH of aqueous phase environmental media in the field. On the occasion that LSASD field personnel determine that any of the procedures described in this section cannot be used to obtain pH measurements of the media being sampled, and that another method must be used to obtain said measurements, the variant instrument and/or measurement procedure will be documented in the field logbook and subsequent investigation report, along with a description of the circumstances requiring its use. Mention of trade names or commercial products in this operating procedure does not constitute endorsement or recommendation for use.

Uncontrolled When Printed

1 General Information

1.1 Documentation/Verification

This procedure was prepared by persons deemed technically competent by LSASD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on LSASD's local area network (LAN). The Document Control Coordinator is responsible for ensuring that the most recent version of the procedure is placed on LSASD's LAN and for maintaining records of review conducted prior to its issuance.

1.2 General Precautions

1.2.1 Safety

Proper safety precautions must be observed when conducting field pH measurements. Refer to the LSASD Safety, Health and Environmental Management Program Procedures and Policy Manual (Most Recent Version) and any pertinent site-specific Health and Safety Plans (HASPs) for guidelines on safety precautions. These guidelines, however, should only be used to complement the judgment of an experienced professional. Address chemicals that pose specific toxicity or safety concerns and follow any other relevant requirements, as appropriate.

1.2.2 Procedural Precautions

All field pH measurements pertinent to the sampling event should be recorded in the field logbook for the event. All records, including a unique, traceable identifier for the instrument, such as a property number or serial number, should be entered according to the procedures outlined in the LSASD Operating Procedure for Logbooks (LSASDPROC-010) and the LSASD Operating Procedure for Equipment Inventory and Management, (LSASDPROC-108). Care should be taken not to contaminate standards and samples and verify the expiration date of all standards prior to use. All meters should be calibrated, operated and maintained according to the manufacturer's specifications.

2 Quality Control

All pH meters will be maintained and operated in accordance with the manufacturer's instructions and the LSASD Operating Procedure for Equipment Inventory and Management (LSASDPROC-108). Before a meter is taken to the field, it will be properly calibrated or verified, according to Section 3.2 of this procedure, to ensure it is operating properly. These calibration and verification checks will be documented and maintained in a logbook.

Uncontrolled When Printed

The ambient temperature in the immediate vicinity of the meter should be measured and recorded in the field logbook to ensure the instrument is operated within the manufacturer's specified range of operating temperatures, although this is typically not necessary for ecological studies. For instruments that are deployed for *in-situ* measurements, the temperature of the medium being monitored should be measured and recorded in the logbook prior to deployment. *In-situ monitoring equipment may be utilized in unattended deployments where autonomous logging may preclude temperature measurement prior to deployment. Because in-situ instrumentation generally has a wide range of operating temperatures, the field investigator may utilize professional judgment in determining if the operating environment is suitable for unattended deployment.*

If at any time during a field investigation, it appears that the environmental conditions could jeopardize the quality of the measurement results, the measurements will be stopped. This will be documented in the field logbook.

3 Field pH Measurement Procedures

3.1 General

pH is defined as the negative logarithm of the effective hydrogen-ion concentration. The ion selective pH electrode measures the difference in potentials between the two sides in a glass electrode. The circuit is closed through internal solutions of the electrode and the external solution that is being measured and the pH meter. As the electrode is immersed in the test solution the glass bulb senses the positive charged hydrogen ions as millivolts (mV). The pH meter measures the difference between an internal electrode and a reference electrode. This mV reading is then read by the meter and is displayed in pH units. For routine work, a pH meter accurate and reproducible to within 0.2 Standard Units (S.U.) is suitable. For NPDES compliance monitoring, the pH meter should be accurate and reproducible to within 0.1 S.U. Both meters should have a range of 0 to 14 S.U. and be equipped with a temperature-compensation adjustment. Modern pH meters usually have a protective housing around the glass bulb but are sensitive scientific instruments and should be handled with care. Most pH electrodes last from one to two years, depending on the deployment environment and if proper storage solution was used during periods of inactivity.

3.2 Instrument Calibration

Many brands of instruments are commercially available for the measurement of pH incorporating a wide variety of technologies. The manufacturer's instruction manual should be consulted for specific procedures regarding their calibration, maintenance and use. Calibration of any measurement instrument must be conducted and/or verified prior to each use or on a daily basis, whichever is most appropriate. At a minimum, a two-point calibration should be conducted to ensure the accuracy of the meter. The following are basic guidelines for calibration/verification and are provided as an example (procedure may vary based on the instrument used):

Uncontrolled When Printed

1. Verify the meter's internal temperature sensor (thermistor) against a National Institute of Standards and Technology (NIST) traceable thermometer and note any differences between the thermistor and the NIST-traceable thermometer in the logbook. If the temperatures do not agree within ± 4°C, the unit or probe must be repaired or replaced. Alternatively, if the meter can be used in a manual temperature compensation mode, the NIST-traceable thermometer may be used for temperature readings and the necessary corrections applied. Check and record the temperatures of the standards and the samples.

2. If the pH range of the sample is not known, the pH of the sample to be tested should be estimated either from historical data or by using a four-color pH indicator paper or equivalent. Using this information, calibrate the pH meter with the buffers that bracket the expected pH range. Buffer solutions are commonly pH 4, 7 and 10. It may be possible to configure the pH meter so that it can be standardized with buffers other than those in the default configuration. Note that buffer values are temperature specific (reading true at 25°C) and be sure to input the correct buffer calibration value for the given temperature in step 3 below. Some pH probes are capable of Automatic Temperature Compensation (ATC) and will recognize the correct temperate corrected value of the calibration standard.

3. Immerse the probe in the required buffer solutions and record pre-cal values (pH 7 buffer is typically the first cal point). Then re-immerse the probe to calibrate to the correct pH buffer value, also recording the post-cal value. Rinse the probe with de-ionized water and blot dry or otherwise remove excess rinse water between the different buffer solutions. Record the buffer values and temperatures used to calibrate the meter.

4. Rinse the probe with de-ionized water, blot dry or otherwise remove excess rinse water and immerse it into the appropriate buffer and read as a measurement. If the meter reads within ± 0.2 S.U. of the known value of the buffer (for general applications such as ecological studies) or ± 0.1 S.U. (for regulatory applications such as NPDES or drinking water programs), record the value indicated by the meter. If the meter is outside of the acceptable accuracy range, it should be recalibrated. If it is still outside of the acceptable accuracy range after the second calibration, the electrode and/or meter should be replaced.

5. Once the meter has been properly calibrated and verified (steps 1-4 above), it is ready for use. Rinse the probe with de-ionized water and store it according to manufacturer's recommendations. Certain instruments may require being left on until all measurements are performed and the results are recorded. When collecting measurements from grab samples, certain instrument manufacturers recommend that an intermediate check(s) be performed by periodically checking the meter against a known calibration buffers if used for extended periods (> 4 hrs).

6. Unless the manufacturer indicates that the meter maintains its calibration after being turned off, meters must be re-calibrated if they are turned off during their period of use.

   Note: If multi-parameter sondes are used, calibrate according to the manufacturer's specifications and procedural directions. Calibration procedures for sondes for *in-situ* monitoring may in some cases be different than those for field pH meters using open probes. Those procedures are documented in LSASD's SOP listed as: LSASDPROC-111-R4, In-Situ

Uncontrolled When Printed

3.3 Field Measurement Procedures

Measurements in the field may occur under several conditions, requiring various specific procedures. A pH probe should never be placed in an analytical sample to avoid cross-contamination, only sample aliquots should be used as a surrogate for sample pH measurements. Use of the word *sample* below implies that a sample aliquot has been collected.

3.3.1 Grab Sample Measurements

These procedures should be followed when conducting field pH measurements of grab sample:

1. Collect a sample. If the meter's thermistor is to be used for the temperature of record for the measurement activity, the temperature should be read as soon as the reading stabilizes and prior to measuring the pH.

   Note 1a: When the pH meter response is slow, unstable, or non-reproducible, it may be necessary to check the conductivity. If the conductivity is lower than 20 to 30 µmhos/cm, it is permissible to add 1 ml of 1M potassium chloride solution per 100 ml of sample to improve response time for the probe. Recheck the pH and record.

   Note 1b: If the pH measurements are to be used for RCRA regulatory purposes and when the pH approaches the alkaline end ($pH \geq 11.0$) of the scale, the pH measurements should be made by a qualified analyst using laboratory quality equipment to control the sample at 25°C ± 1°C.

2. Immerse the lower part of the probe in the sample. Typically, in the field, the pH probe is not kept away from container bottom or sides during calibration, or during field readings in an overtopping cell, as it is not practical. End of day readings are also performed the same way. Allow ample time for the probe to equilibrate with the sample.

3. While suspending the probe in the sample container, record the pH.

4. Rinse the probe with de-ionized water and replace end cap if applicable. For longer term storage, place probe in the manufacturer's recommended storage solution.

3.3.2 Overtopping Cell Measurements

Often during groundwater sampling, an overtopping cell may be used with purge water constantly flowing through the cell during purging. These procedures should be followed when conducting field pH measurements using an overtopping cell:

1. Immerse the bottom portion of the probe in the open-top container being used for purge water

Uncontrolled When Printed

flow-through. Allow it to equilibrate with the purge water and stabilize until the meter indicates that it is ready for readings. Readings may be recorded at certain timed intervals in the field, prior to collecting the sample for laboratory analysis.

2. When finished at one sampling station during the day and moving to the next, the protective end cap should be placed on the probe until ready for use again.

3.3.3 *In-Situ* Measurements

These procedures should be followed when conducting *in-situ* field pH measurements:

1. Place the probe/sonde into the media to be measured and allow the pH and temperature readings to stabilize. Once the readings have stabilized, record the measurements in the logbook.

2. When deploying meters for extended periods of time, ensure the measurement location is representative of average media conditions.

   Note: If multi-parameter sondes are used for pH measurement, procedures such as for depth profiling of pH, may be different than for pH meters with open probes. Those procedures are documented in LSASD's SOP listed as: LSASDPROC-111-R4, In-Situ Water Quality Monitoring.

3.3.4 Sample Preservation Verification

When verifying the pH for sample preservation in a field sample collected for laboratory analysis, this procedure should be followed:

1. Pour a small amount of sample from bottle over a pH strip to determine if the sample has been preserved to the specified pH range; meters are not needed. Be sure to properly dispose of used pH strips, as contaminant level is likely unknown.

3.4 Operational Check

Even though it is not necessary to re-calibrate pH meters at regular intervals during the day, depending on the instrument, it may be appropriate to occasionally perform operational checks to determine if site conditions, such as an increase in temperature, have impacted the meter's performance. If an operational check is warranted, the following procedure should be followed to ensure that the performance of the meter has not changed.

1. While in use, periodically check the pH by rinsing the probe with de-ionized water, blot dry or

Uncontrolled When Printed

otherwise remove excess rinse water and immerse it into the appropriate buffer solution. If the measured pH differs by $\geq$ 0.2 S.U. or 0.1 S.U. (depending on the application) from the buffer solution, the meter must be re-calibrated.

A post-operation instrument verification check will be performed using the appropriate buffer(s) at the end of the day or after all measurements have been taken for a particular period of operation. These measurements must be recorded in the field logbook.

OPERATING PROCEDURE	
Title: Field Specific Conductance Measurement	ID: LSASDPROC-101-R7
Issuing Authority: LSASD Field Branch Chief	
Effective Date: May 5, 2020	Review Date: May 5, 2023

Purpose

This document describes procedures, methods and considerations to be used and observed when conducting field specific conductance measurements in aqueous phase environmental media, including groundwater, surface water and certain wastewaters.

Scope/Application

The procedures contained in this document are to be used by field investigators when measuring the specific conductance of aqueous phase environmental media in the field. On the occasion that LSASD field investigators determine that any of the procedures described in this section cannot be used to obtain specific conductance measurements of the media being sampled, and that another method must be used to obtain said measurements, the variant instrument and/or measurement procedure will be documented in the field logbook, along with a description of the circumstances requiring its use. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

1 General Information

1.1 Documentation/Verification

This procedure was prepared by persons deemed technically competent by LSASD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the LSASD local area network (LAN). The Document Control Coordinator is responsible for ensuring the most recent version of the procedure is placed on the LAN and for maintaining records of review conducted prior to its issuance.

1.2 General Precautions

1.2.1 Safety

Proper safety precautions must be observed when conducting field specific conductance measurements. Refer to the LSASD Safety, Health and Environmental Management Program Procedures and Policy Manual and any pertinent site-specific Health and Safety Plans (HASPs) for guidelines on safety precautions. These guidelines, however, should only be used to complement the judgment of an experienced professional. Address chemicals that pose specific toxicity or safety concerns and follow any other relevant requirements, as appropriate.

1.2.2 Procedural Precautions

All field specific conductance measurements pertinent to the sampling event, including a unique, traceable identifier for the instrument, such as a property number or serial number, should be recorded in the field logbook for the event. All records should be entered according to the procedures outlined in the LSASD Operating Procedure for Logbooks (LSASDPROC-010, most recent version).

Care should be taken to not contaminate standards and samples and verify the expiration date of all standards prior to use. All meters should be calibrated, operated and maintained according to the manufacturer's specifications.

2 Quality Control

All specific conductance meters will be maintained and operated in accordance with the manufacturer's instructions and the LSASD Operating Procedure for Equipment Inventory and Management (LSASDPROC-108, most recent version). Before a meter is taken to the field, it will be properly calibrated or verified, according to Section 3.2 of this procedure, to ensure it is operating properly. These calibration and verification checks will be documented and maintained in a logbook.

The ambient temperature in the immediate vicinity of the meter should be measured and recorded in the field logbook to ensure the instrument is operated within the manufacturer's specified range of operating temperatures. For instruments that are deployed for in-situ measurements, the temperature of the medium being monitored should be measured and recorded in the logbook prior to deployment. *In-situ monitoring equipment may be utilized in unattended deployments where autonomous logging may preclude*

temperature measurement prior to deployment. Because in-situ instrumentation generally has a wide range of operating temperatures, the field investigator may utilize professional judgment in determining if the operating environment is suitable for unattended deployment.

If at any time during a field investigation it appears that the environmental conditions could jeopardize the quality of the measurement results, the measurements will be stopped. This will be documented in the field logbook.

3 Field Specific Conductance Measurement Procedures

3.1 General

Specific conductance is a measure of the ability of an aqueous solution to conduct an electric current and is customarily reported in microsiemens per centimeter (µS/cm) or micromhos per centimeter (µmhos/cm) at 25°C. It is important to note that if the specific conductance measurements are for NPDES reporting purposes, the meter and conductivity cell should be verified by comparing against a laboratory meter with a platinum-electrode type conductivity cell.

3.2 Instrument Calibration and Verification

Many brands of instruments are commercially available for the measurement of specific conductance incorporating a wide variety of technologies. The manufacturer's instruction manual should be consulted for specific procedures regarding their calibration, maintenance and use. Calibration of any measurement instrument must be conducted and/or verified prior to each use or on a daily basis, whichever is most appropriate.

Conductivity is affected by temperature; therefore, for instruments that do not automatically compensate for temperature, the user should document temperature first so that appropriate adjustments can be made in accordance with the manufacturer's instructions and/or method. The following are basic guidelines for calibration/verification and are provided as an example:

1. Verify the meter's internal temperature sensor (thermistor) against a National Institute of Standards and Technology (NIST) traceable thermometer and note any differences between the thermistor and the NIST-traceable thermometer in the logbook. If the temperatures do not agree within ± 4°C, the unit must be repaired or replaced. Alternatively, if the meter can be used in a manual temperature compensation mode, the NIST-traceable thermometer may be used for temperature readings and the necessary corrections applied. Check and record the temperatures of the standards and the samples.

2. Rinse the probe with de-ionized water and blot dry before conducting the following calibration and verification checks.

3. Immerse the probe in the first standard solution and calibrate or verify the meter against that solution. Fresh standards should be used for each calibration. After the initial standard, calibrate and/or verify the meter using additional standards, as appropriate. Rinse the probe with de-ionized water and blot dry or otherwise remove excess rinse water between the

different standards. Record the standard values/temperatures used to calibrate or verify the meter.

Note: Some instruments require that calibration standards reflect the anticipated specific conductance of the media being measured.

4. Some meters will auto-recognize standards during calibration. For example, the Thermo Star Series meter will auto-recognize standards 1413 µS/cm, 100 µS/cm and 12.9 mS/cm. If the meter is calibrated in a manner where it does not auto-recognize the standard, and the meter is not accurate to ± 10 % of the standard solution(s) known values, the meter or probe should be repaired or replaced. If this condition can be corrected by adjusting the cell constant of the probe, refer to the instruction manual and make the adjustment. Note: The Thermo Star A325 units primarily used for ground water investigations should be set to Temperature Correction mode nLFn for best results.

5. After calibration is complete, place the probe back into the calibration standard used and record a post-calibration reading. Record a post calibration reading for each standard used. If the meter is not accurate to within ± 10 % of the standard solution(s) known values, it should be recalibrated. If it is still outside of the acceptable accuracy range after the second calibration, the probe and/or meter should be replaced.

6. Once the meter has been properly calibrated and verified (steps 1-5 above), it is ready for use. Rinse the probe with de-ionized water and store it in the manufacturer's recommended storage solution. Certain meters may require that the instrument be left on until all sample measurements are performed and the results are recorded. When collecting measurements from grab samples, certain instrument manufacturers recommend that an intermediate check(s) be performed by periodically checking the meter against the known calibration standards if used for extended periods (> 4 hrs).

3.3 Sample Measurement Procedures

The following procedures should be followed when conducting field specific conductance measurements of grab samples:

1. Collect the sample, check and record its temperature.

2. Correct the instrument's temperature adjustment to the temperature of the sample (if required).

3. Immerse the probe in the sample keeping it away from the sides and bottom of the container. It is important that the center portion of the probe be wetted by the sample.

4. Allow meter to stabilize. Record the results in a logbook.

5. Rinse probe with de-ionized water.

The following procedures should be followed when conducting in-situ field specific conductivity measurements:

1. Place the probe into the media to be measured and allow the specific conductivity and temperature readings to stabilize. Once the readings have stabilized, record the measurements in the logbook.

2. When deploying meters for extended periods of time, ensure the measurement location is representative of average media conditions.

3.4 Operational Checks

Even though it is not necessary to re-calibrate conductivity meters at regular intervals during the day, depending on the instrument, it may be appropriate to occasionally perform operational checks to determine if site conditions, such as an extreme temperature change, have impacted the meter's performance. If an operational check is warranted, the following procedures should be followed to ensure that the performance of the meter has not changed.

Check the conductivity meter with fresh conductivity standard. Rinse the conductivity probe with deionized water, blot dry or otherwise remove excess rinse water and immerse it into the appropriate conductivity standard. If the measured conductivity value is not with ± 10% of the standard, the probe should be re-calibrated. If the probe is still not within ± 10% of the standard, the probe should be repaired or replaced. These measurements must be recorded in the field logbook.

A post-operation instrument verification check should be performed using the appropriate standard(s) at the end of the day or after all measurements have been taken for a particular period of operation. These measurements must be recorded in the field logbook.

Uncontrolled When Printed

1.0 Field Temperature Measurement Procedures

1.1 General

Field temperature measurements may be made with a field thermometer, equipment thermistor, or NIST-traceable thermometer. At a minimum, the temperature measurement device should be capable of measuring in 0.1°C increments.

1.2 Instrument Verification

1.2.1 Field thermometers and thermistors

Temperature measurement devices such as field thermometers and equipment thermistors will be verified against a NIST-traceable thermometer prior to use and should agree within ± 4.0°C. Corrections may be applied for measurements up to ± 4.0°C depending on investigation objectives, but the instrument must be repaired or replaced beyond that range.

Due to the stable nature of thermistors on multi-parameter water quality instruments, thermistors will be checked at the beginning and end of a field study, but do not have to be checked for every calibration during the study. In order to track stability and reliability, the thermistors on these units will be checked against a NIST-traceable thermometer on an annual basis, with the electronic record of these checks maintained on the Ecology Section Sharepoint Site.

In order to provide the most stable readings, thermistor checks against the NIST-traceable thermometer should be conducted in a liquid calibration standard at stabilized room temperature as opposed to air during the saturated air calibration of dissolved oxygen.

Enforcement cases would still require temperature verification for every calibration and end check related to the case.

1.2.2 NIST-traceable thermometer

Verification of the NIST-traceable thermometers that are used to verify temperature measuring devices is accomplished by comparing temperature readings from the NIST-traceable thermometer to a thermometer that has an independent certification of accuracy traceable to the National Institute of Standards and Testing. Current certified thermometers are maintained by the SESD Analytical Support Branch and are called reference thermometers.

Each NIST-traceable thermometer is verified by comparing at least annually against a reference thermometer. If corrections need to be applied, they will be noted in the NIST-traceable thermometer. Depending on investigation objectives, project leaders may decide to apply the correction factor as necessary.

Uncontrolled When Printed

1.3 Inspections

All temperature measurement devices should be inspected for leaks, cracks, and/or function prior to each use.

1.4 Sample measurement procedures for thermometers/thermistors

(Make measurements in-situ when possible)

1. Clean the probe end with de-ionized water and immerse into sample.
2. If not measuring in-situ, swirl the instrument in the sample for mixing and equilibration.
3. Allow the instrument to equilibrate with the sample for at least one minute.
4. Suspend the instrument away from the sides and bottom, if not in-situ, to observe the temperature reading.
5. Record the reading in the log book. For most applications, report temperature readings to the nearest 0.5°C or to the nearest 0.1°C depending on need.

   Note: Always clean the thermometer with de-ionized water or a detergent solution, if appropriate, prior to storage and/or use.

1.5 Units

Degrees Celsius (°C) or Degrees Fahrenheit (°F)

Conversion Formulas:

$°F = (9/5\ °C) + 32$ or $°C = 5/9\ (°F - 32)$

1.6 Quality Control

All thermometers should be maintained and operated in accordance with the manufacturer's instructions and the SESD Operating Procedure for Equipment Inventory and Management (SESDPROC-108). Temperature measurement devices such as pH, conductivity and dissolved oxygen (DO) meter thermistors will be verified against a National Institute of Standards and Technology (NIST)-traceable thermometer before each use as described in Section 3.2.

If at any time during a field investigation, it appears that the environmental conditions could jeopardize the quality of the measurement results, the measurements will be stopped. This will be documented in the field logbook.

1 General Information

1.1 Purpose

This document describes general and specific procedures, methods and considerations to be used and observed when conducting field turbidity measurements in aqueous phase environmental media, including groundwater, surface water and certain wastewaters.

1.2 Scope/Application

The procedures contained in this document are to be used by field personnel when measuring turbidity of various, aqueous phase environmental media in the field. On the occasion that SESD field personnel determine that any of the procedures described in this section cannot be used to obtain turbidity measurements of the media being sampled, and that another method or turbidity measurement instrument must be used to obtain said measurements, the variant instrument and measurement procedure will be documented in the field logbook, along with a description of the circumstances requiring its use. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

1.3 Documentation/Verification

This procedure was prepared by persons deemed technically competent by SESD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the SESD local area network (LAN). The Document Control Coordinator is responsible for ensuring the most recent version of the procedure is placed on the LAN and for maintaining records of review conducted prior to its issuance.

1.5 General Precautions

1.5.1 Safety

Proper safety precautions must be observed when conducting field turbidity measurements. Refer to the SESD Safety, Health and Environmental Management Program (SHEMP) Manual (Most Recent Version) and any pertinent site-specific Health and Safety Plans (HASPs) for guidelines on safety precautions. These guidelines, however, should only be used to complement the judgment of an experienced professional. When using this procedure, minimize exposure to potential health hazards through the use of protective clothing, eye wear and gloves. Address chemicals that pose specific toxicity or safety concerns and follow any other relevant requirements, as appropriate.

1.5.2 Procedural Precautions

All field turbidity measurements pertinent to the sampling event should be recorded in the field logbook for the event. All records should be entered according to the procedures outlined in the SESD Operating Procedure for Logbooks (SESDPROC-010).

COPY

2 Quality Control

All turbidity meters and probes shall be maintained and operated in accordance with the manufacturer's instructions and the SESD Operating Procedure for Equipment Inventory and Management (SESDPROC-108). Before a meter or probe is taken to the field, it shall be properly calibrated or verified, according to Sections 3.2 and 3.3 of this procedure, to ensure it is operating properly. These calibration and verification checks shall be documented and maintained in a logbook.

The ambient temperature in the immediate vicinity of the meter should be measured and recorded in the field logbook to insure the instrument is operated within the manufacturer's specified range of operating temperatures. For instruments that are deployed for in-situ measurements, the temperature of the medium being monitored should be measured and recorded in the logbook prior to deployment. *In-situ monitoring equipment may be utilized in unattended deployments where autonomous logging may preclude temperature measurement prior to deployment. Because in situ instrumentation generally has a wide range of operating temperature, the field investigator may utilize professional judgment in determining if the operating environment is suitable for unattended deployment.*

If at any time during a field investigation, it appears that the environmental conditions could jeopardize the quality of the measurement results, the measurements will be stopped. This will be documented in the field logbook.

3 Field Turbidity Measurement Procedures

3.1 General

Turbidity is caused by suspended and colloidal matter such as clay, silt, organic and inorganic matter and microscopic organisms. Many methods are available for the measurement of turbidity including turbidimeters and optical probes. Turbidity is measured by determining the amount of scatter when a light is passed through a sample.

3.2 Instrument Calibration and Verification

Many brands of instruments are commercially available for the measurement of turbidity incorporating a wide variety of technologies (See Section 3.5 for further discussion). The manufacturer's instruction manual should be consulted for specific procedures regarding their calibration, maintenance and use. Calibration of any measurement instrument must be conducted and/or verified prior to each use or on a daily basis, whichever is most appropriate. Depending on the instrument, the verification and calibration can differ slightly. If the instrument readings do not agree within ± 10 % of the calibration standards, the unit must be recalibrated, repaired or replaced. The following are basic guidelines for calibration/verification of meters and are provided as an example:

3.2.1 Meter Calibration and Verification

HACH 2100Q Turbidimeter:

Portable turbidimeters are calibrated with Formazin Primary Standards. The manufacturer recommends calibration with a primary standard such as StablCal® Stabilized Standards or with formazin standards every three months.

Generally only a calibration verification measurement is required in the field; however, if a calibration is needed, record a post calibration reading for each calibration standard used.

Meter Verification:

1. Push **Verify Cal** to enter the Verify menu.

2. Gently invert the liquid standard several times prior to insertion into meter. Insert the 10.0 NTU (or other defined value) Verification Standard and close the Lid.

3. Push **Read**. The display shows "Stabilizing" and then shows the result and tolerance range.

COPY

4. Push **Done** to return to the reading display. Repeat the calibration verification if the verification failed. If a meter is unable to pass verification, then that meter will need to be calibrated.

Meter Calibration:

1. Push the **CALIBRATION** key to enter the Calibration mode. Follow the instructions on the display. **Note:** Gently invert each standard several times before inserting the standard and use a non-abrasive, lint-free paper or cloth to wipe off the standards.

2. Insert the 20 NTU StablCal Standard and close the lid. Push **Read**. The display shows "Stabilizing" and then shows the result. Record the result.

3. Repeat Step 2 with the 100 NTU and 800 NTU StablCal Standard. Record both results.

4. Push **Done** to review the calibration details.

5. Push **Store** to save the results. After a calibration is complete, the meter automatically goes into the Verify Cal mode.

3.2.2 Probe Calibration and Verification

The manufacturer's instruction manual should be consulted for specific procedures regarding probe's calibration, maintenance and use. Their calibration must be conducted and/or verified prior to each use or on a daily basis, whichever is most appropriate. The following are basic guidelines for calibration/verification of probes and are provided as an example:

1. Turn the meter "ON" and allow it to stabilize

2. Immerse the probe in the first standard solution and calibrate the probe against the solution.

3. Rinse the probe with de-ionized water, remove excess rinse water and calibrate the probe using additional standards as appropriate.

4. Record the standard values used to calibrate the meter.

COPY

3.3 Sample Measurement Procedures

Depending on the meter, the sample measurement procedure can differ slightly.

3.3.1 Grab Sample Measurement

These procedures should be followed when conducting turbidity measurements of grab samples:

1. Collect a representative sample and pour off enough to fill the cell to the fill line (about 15 mL) and replace the cap on the cell.

2. Gently wipe off excess water and any streaks from surface of sampling vial.

3. Turn instrument on. Place the meter on a flat, sturdy surface. Do not hold the instrument while making measurements.

4. Insert the sample cell in the instrument so the diamond or orientation mark aligns with the raised orientation mark in the front of the cell compartment. Close the lid.

5. If appropriate, select manual or automatic range selection by pressing the range key.

6. If appropriate, select signal averaging mode by pressing the Signal Average key. Use signal average mode if the sample causes a noisy signal (display changes constantly).

7. Press Read. The display will show ---- NTU. Then the turbidity is displayed in NTU. Record the result to the correct range dependent significant digits as required by EPA Method 180.1 Rev. 2.0 (USEPA, 1993) and SM 2130B (APHA, 1992) (Table 1).

8. Rinse the cell with de-ionized water or rinse out with sample water prior to the next reading.

COPY

Table 1: Reporting Requirements (APHA, 1992)

Turbidity Range *NTU*	Report to the Nearest *NTU*
0–1.0	0.05
1–10	0.1
10–40	1
40–100	5
100–400	10
400–1000	50
>1000	100

3.3.2 In-Situ Measurement

These procedures should be followed when conducting in-situ turbidity measurements:

1. Place the probe into the media to be measured and allow the turbidity reading to stabilize. Once the reading has stabilized, record the measurement in the logbook.

2. When deploying meters for extended periods of time, ensure the measurement location is representative of average media conditions.

3.4 Operational check

Even though it is not necessary to re-calibrate turbidity meters at regular intervals during the day, depending on the instrument, it may be appropriate to occasionally perform operational checks to determine if site conditions, such as an increase in temperature, have impacted the meter's performance. If an operational check is warranted, the following procedure should be followed to ensure that the performance of the meter has not changed.

While in use, periodically check the turbidity by rinsing the probe with de-ionized water, blot dry or otherwise remove excess rinse water and immerse it into the appropriate calibration standard. If the measured turbidity differs by ± 10 % (depending on the application) from the calibration standard, the meter must be re-calibrated.

A post-operation instrument verification check will be performed using the appropriate standard(s) at the end of the day or after all measurements have been taken for a particular period of operation. These measurements must be recorded in the field logbook.

COPY

3.5 Units and Application

Due to the availability of various technologies for measuring turbidity, the USGS (United States Geological Survey) in collaboration with ASTM International (American Society for Testing and Materials) has determined that data collected using different methods are not directly comparable and should be reported in units reflecting the specific technology used (USGS 2004; ASTM International 2012) (Table 2).

Measurements taken for regulatory purposes (i.e. National Primary Drinking Water Regulations (NPDWR) monitoring, National Pollution Discharge Elimination System (NPDES) reporting) must be in compliance with EPA approved methods. Approved methods for Clean Water Act programs and Safe Drinking Water Act programs can be found in 40 C.F.R. § 136.3 and 40 C.F.R. § 141.74(a)(1), respectively.

Project leaders should consult the decision tree depicted in Figure 1 to determine the appropriate turbidity method that will meet the project specific Data Quality Objectives. For more detailed information on the different methods and their associated units, refer to the USGS National Field Manual for the Collection of Water-Quality Data, Section 6.7 (USGS 2005) and ASTM designation D7315 (ASTM International 2012). A sensor specific spreadsheet detailing methods and associated units can be found on the USGS Field Manual website under turbidity parameter and methods codes (USGS 2012).

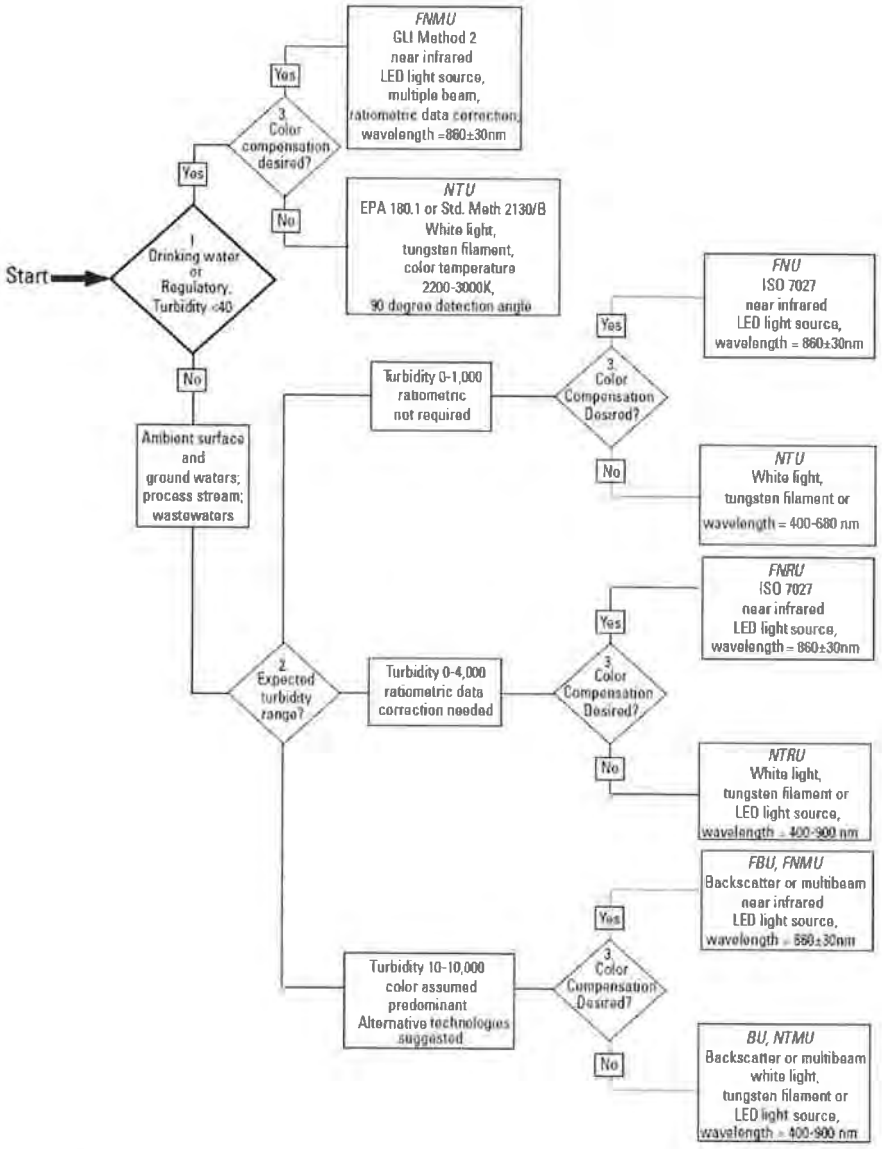

Figure 1: Turbidity Method Decision Tree, adapted from Figure 6.7-2 (USGS 2005)

COPY

Table 2: Turbidity Technology, Units, Application, & Design (adapted from ASTM International 2012)

Design and Reporting Unit	Prominent Application	Key Design Features
Nephelometric non-ratio (NTU)	White light turbidimeters. Comply with USEPA Method 180.1 for low level turbidity monitoring.	Detector centered at 90° relative to the incident light beam. Uses a white light spectral source.
Ratio White Light turbidimeters (NTRU)	Complies with ISWTR regulations and Standard Method 2130B. Can be used for both low and high level measurement.	Used a white light spectral source. Primary detector centered at 90°. Other detectors located at other angles. An instrument algorithm uses a combination of detector readings to generate the turbidity reading.
Nephelometric, near-IR turbidimeters, non-ratiometric (FNU)	Complies with ISO 7027. The wavelength is less susceptible to color interferences. Applicable for samples with color and good for low level monitoring.	Detector centered at 90° relative to the incident light beam. Uses a near-IR (780–900 nm) monochromatic light source.
Nephelometric near-IR turbidimeters, ratio metric (FNRU)	Complies with ISO 7027. Applicable for samples with high levels of color and for monitoring to high turbidity levels.	Uses a near-IR monochromatic light source (780–900 nm). Primary detector centered at 90°. Other detectors located at other angles. An instrument algorithm uses a combination of detector readings to generate the turbidity reading.
Surface Scatter Turbidimeters (NTU)	Turbidity is determined through light scatter from or near the surface of a sample.	Detector centered at 90° relative to the incident light beam. Uses a white light spectral source.
Formazin Back Scatter (FBU)	Not applicable for regulatory purposes. Best applied to high turbidity samples. Backscatter is common with but not all only probe technology and is best applied in higher turbidity samples.	Uses a near-IR monochromatic light source in the 780–900 nm range. Detector geometry is between 90° and 180° relative to the incident light beam.
Backscatter Unit (BU)	Not applicable for regulatory purposes. Best applied for samples with high level turbidity.	Uses a white light spectral source (400–680 nm range). Detector geometry is between 90° and 180° relative to the incident light beam.
Formazin attenuation unit (FAU)	May be applicable for some regulatory purposes. This is commonly applied with spectrophotometers. Best applied for samples with high level turbidity.	Detector is geometrically centered at 0° relative to incident beam (attenuation). Wavelength is 780–900 nm.
Light attenuation unit (AU)	Not applicable for some regulatory purposes. This is commonly applied with spectrophotometers.	Detector is geometrically centered at 0° relative to incident beam (attenuation). Wavelength is 400–690 nm.
Nephelometric Turbidity Multibeam Unit (NTMU)	Is applicable to EPA regulatory method GLI Method 2. Applicable to drinking water and wastewater monitoring applications.	Detectors are geometrically centered at 0° and 90°. An instrument algorithm uses a combination of detector readings, which may differ for turbidities varying magnitude.

Revision History

The top row of this table shows the most recent changes to this controlled document. For previous revision history information, archived versions of this document are maintained by the SESD Document Control Coordinator on the SESD local area network (LAN).

History	Effective Date
SESDPROC-106-R4, *Field Measurement of Dissolved Oxygen*, replaces SESDPROC-106-R3 **General:** Corrected any typographical, grammatical, and/or editorial errors. In addition, any references to former Division organizational structure was updated to reflect current structure. **Title Page:** Changed the Author from Hunter Johnson to Nathan Barlet. Changed the Field Quality Manager from Bobby Lewis to Hunter Johnson. Updated cover page to represent SESD reorganization. **Table of Contents:** Added Sections 3.2.1 Water-Saturated Air Method, 3.2.2 Air-Saturated Water Method, and 3.2.3 Zero-DO Verification & 2-Point Calibration. Changed Section 3.5 from "Operational Check" to "Operational Verification." Updated page numbers. **Section 1.4:** Added the citations for Benson and Krause (1980), Benson and Krause (1984), USGS (2013*a*), and USGS (2013*b*) as references, **Section 3.1:** Changed "volume of oxygen contained in a volume of water" to "mass of molecular oxygen contained in a volume of water." Changed "pressure" in first paragraph and third bullet point to "atmospheric pressure." **Section 3.2:** Added "However, some optical DO meters are capable of a two-point calibration at 0% and 100% saturation, refer to Section 3.2.3 for applicability." Added Section 3.2.1 Water-Saturated Air Method, which includes information on the calibration procedure for the water-saturated air method. Added "Allow at least 10-15 minutes for the temperature and dissolved oxygen readings to equilibrate. Ensure that water droplets are removed from the luminescence cap or Clark cell membrane and thermistor before calibration. Refer to Section 3.5 for calibration verification procedure." Added Section 3.2.2 Air-Saturated Water Method, which includes information on the calibration procedure for the air-saturated water	April 12, 2017

COPY

method. Added "Refer to Section 3.5 for calibration verification procedure." Added Section 3.2.3 Zero-DO Verification & 2-Point Calibration. Added "It is recommended that a zero-DO verification is conducted periodically or when concentrations are expected to be below 1 mg/l (USGS, 2013*a*). A zero-DO solution can be prepared by dissolving 1 gram of sodium sulfite in 1 liter of deionized water. This should be made fresh weekly or as needed. If the unit is equipped with a wiper, it should be removed before immersing in zero-DO solution. The reading should not exceed a concentration of 0.2 mg/l dissolved oxygen in the zero-DO solution. For Clark cells that exceed this concentration, replace the electrolyte and membrane before repeating the zero-DO verification process. For optical probes that read above 0.2 mg/l in zero-DO solution, replace the sensor cap if it is expired or perform a 2-point calibration if applicable. Some optical DO probes are capable of 2-point calibrations using a zero-DO solution and the air-saturated water method discussed in Section 3.2.2. Refer to the manufacturer's instruction manual for the appropriate 2-point calibration procedure. Ensure that the probe is thoroughly rinsed of zero-DO solution after verification or calibration to avoid measurement interferences caused by residual sodium sulfite." **Section 3.4:** Changed the fifth bullet point to read "The DO meter should be capable of auto-correcting for specific conductivity/salinity or a separate instrument should be used to measure specific conductivity/salinity so that the final DO measurement(s) can be corrected." **Section 3.5:** Changed the title from "Operational Check" to "Operational Verification." Changed first paragraph to read "A post-calibration and post-operation instrument verification check should be performed using one of the techniques described in Sections 3.2.1 and 3.2.2 or 3.2.3 (for 2-point calibrations) to quantify potential instrument drift during use. A verification check will be performed after a calibration and at the end of all measurements" Changed second paragraph to read "It may be appropriate to verify the calibration of a DO meter periodically during the course of a day's measurements when conducting individual measurements. A DO probe may be re-calibrated throughout the day if drift is occurring. The verification DO concentration should be measured and recorded in the field logbook prior to any instrument adjustment." Also added the sentence "For long-term deployments a post-operation verification should be performed at the end of the deployment." Added third paragraph which reads "Verification is done by comparing a post-calibration or post-operation reading at 100% saturation conditions to a DO solubility table value at the ambient air/water	

COPY

temperature and barometric pressure. Post-calibration and post-operation readings should not exceed a maximum of ± 0.2 mg/l from the DO solubility table value. DO solubility tables can be accessed via the U.S. Geological Survey's DOTABLES software (USGS, 2013*b*) which are based on equations from Benson and Krause (1980; 1984)."

1 General Information

1.1 Purpose

This document describes methods and considerations to be used and observed when conducting field measurements of dissolved oxygen in surface water, treated wastewater and in gas media for specific applications (e.g., reaeration measurement).

1.2 Scope/Application

On the occasion that SESD field investigators determine that any of the procedures described in this section are inappropriate, inadequate or impractical and that another method must be used to obtain a measurement of dissolved oxygen, the alternate procedure will be documented in the field log book, along with a description of the circumstances requiring its use. Mention of trade names or commercial products in this operating procedure does not constitute endorsement or recommendation for use.

1.3 Documentation/Verification

This procedure was prepared by persons deemed technically competent by SESD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the SESD Local Area Network (LAN). The Document Control Coordinator (DCC) is responsible for ensuring the most recent version of the procedure is placed on the LAN and for maintaining records of review conducted prior to its issuance.

1.5 General Precautions

1.5.1 Safety

Refer to the SESD Safety, Health and Environmental Management Program Procedures and Policy Manual and any pertinent site-specific Health and Safety Plans (HASPs) for guidelines on safety precautions. These guidelines, however, should only be used to complement the judgment of an experienced professional. When using this procedure, minimize exposure to potential health hazards through the use of protective clothing, eye wear and gloves. Address chemicals that pose specific toxicity or safety concerns and follow any other relevant requirements, as appropriate.

Appropriate precautions should be observed when working in and around bodies of water and on boats. Be aware of fast flowing waters, waterway obstructions such as dams, and other vessels on the water.

COPY

2 Quality Control

All dissolved oxygen meters will be maintained and operated in accordance with the manufacturer's instructions and the SESD Operating Procedure for Equipment Inventory and Management (SESDPROC-108). Before a meter is utilized in the field, it will be calibrated and verified, according to Section 3.2 of this procedure, to ensure it is operating properly. These calibration and verification checks will be documented and maintained in a logbook.

For in-situ measurements, an instrument warm-up period appropriate for that instrument should be provided. Consult manufacturer's documentation for appropriate warm-up time.

The ambient temperature in the immediate vicinity of the meter should be measured and recorded in the field logbook to insure the instrument is operated within the manufacturer's specified range of operating temperatures. For instruments that are deployed for in-situ measurements, the temperature of the medium being monitored should be measured and recorded in the logbook prior to deployment. *In-situ monitoring equipment may be utilized in unattended deployments where autonomous logging may preclude temperature measurement prior to deployment. Because in situ instrumentation generally has a wide range of operating temperature, the field investigator may utilize professional judgment in determining if the operating environment is suitable for unattended deployment.*

Following instrument use, an end check should be performed using one of the techniques described in Section 3.2 to quantify potential instrument drift during use.

If at any time during a field investigation, it appears that the environmental conditions could jeopardize the quality of the measurement results, the measurements will be stopped. This will be documented in the field logbook.

COPY

3 Field Measurement of Dissolved Oxygen

3.1 General

Dissolved oxygen can be defined as the mass of molecular oxygen contained in a volume of water. The solubility of oxygen in water is dependent on the water temperature, salinity and atmospheric pressure.

- As the temperature of the water decreases, the solubility of oxygen increases.
- As salinity increases, the solubility of oxygen decreases.
- As atmospheric pressure decreases (altitude increases), the solubility of oxygen decreases.

Several methods for measurement of dissolved oxygen in water are available utilizing a variety of technologies. When measuring dissolved oxygen for compliance with the National Pollutant Discharge Elimination System (NPDES) Program, only approved methods will be used. Approved methods can be found in the Code of Federal Regulations (CFR) 40 CFR Part 136.

3.1.1 Clark Cell Probes

Clark cell probes utilize an oxygen permeable membrane that covers an electrolytic cell which consists of a cathode and an anode. The anode acts as a reference electrode. After passing through the permeable membrane, the oxygen is reduced by an applied potential voltage that is referenced to the anode. The reduction current at the cathode is directly proportional to the partial pressure of oxygen in liquid, expressed as %-air saturation. The concentration of oxygen, in mg/l, is calculated based on the %-air saturation reading and the solubility of oxygen in water at the sample temperature.

In general, sample collection using a DO probe requires only lowering the probe into the sample media and recording or logging the results. The probe should be lowered gently to prevent damage to the membrane and gently turned when initially lowered to remove any attached air bubbles. If the instrument requires the use of a stirrer, the stirrer should be turned on before recording any readings. Prior to use, the instrument should be calibrated and any manufacturer specified warm-up period should be observed.

3.1.2 Luminescent Probes

Luminescent dissolved oxygen probes employ a light emitting diode (LED) to provide incident light, which excites the oxygen-sensitive luminescent-dye

COPY

molecule substrate of the sensor. After dissipation of the excitation energy, longer-wavelength light is emitted (luminescence). The magnitude of steady-state luminescence (intensity) is measured by the sensor and is inversely proportional to the dissolved oxygen concentration.

Sample collection with this type of probe should follow the sample procedures described in the second paragraph of Section 3.1.2 for Clark Cell probes.

3.2 Calibration

Many brands of instruments are commercially available for *in-situ* measurement of dissolved oxygen using Clark cell probes and luminescent probes. The manufacturer's instruction manual should be consulted for specific procedures regarding their calibration, maintenance and use. Calibration of any measurement instrument must be conducted and/or verified prior to each use or on a daily basis, whichever is most appropriate.

In general, calibrations should be conducted at temperatures and pressures as close as possible to those of the sample media for the most accurate measurements. Due to the sensitivity of dissolved oxygen measurements to changes in temperature, the temperature probe or thermistor should be verified using a NIST traceable thermometer prior to each calibration. Most dissolved oxygen meters utilize a one-point calibration which is generally performed using either water-saturated air or air-saturated water. However, some optical DO meters are capable of a two-point calibration at 0% and 100% saturation, refer to Section 3.2.3 for applicability.

3.2.1 Water-Saturated Air Method

When using the water-saturated air method, the probes should be placed in a 100% relative humidity environment open to ambient air temperature and barometric pressure. Allow at least 10-15 minutes for the temperature and dissolved oxygen readings to equilibrate. Ensure that water droplets are removed from the luminescence cap or Clark cell membrane and thermistor before calibration. Refer to Section 3.5 for calibration verification procedure.

3.2.2 Air-Saturated Water Method

When using air-saturated water for calibration, an aeration device such as an aquarium pump with a diffusion stone should be placed in a vessel containing tap water. The water in the vessel should be aerated for a minimum of one hour at a

COPY

constant temperature. Saturation should be verified by placing the dissolved oxygen probe in the vessel and monitoring the temperature and dissolved oxygen readings for stabilization. Avoid placing the probe in the direct stream of air bubbles. Bubbles can accumulate on the probe surface and cause erroneous readings. Refer to Section 3.5 for calibration verification procedure.

3.2.3 Zero-DO Verification and 2-Point Calibration

It is recommended that a zero-DO verification is conducted periodically or when concentrations are expected to be below 1 mg/l (USGS, 2013*a*). A zero-DO solution can be prepared by dissolving 1 gram of sodium sulfite in 1 liter of deionized water. This should be made fresh weekly or as needed. If the unit is equipped with a wiper, it should be removed before immersing in zero-DO solution. The reading should not exceed a concentration of 0.2 mg/l dissolved oxygen in the zero-DO solution. For Clark cells that exceed this concentration, replace the electrolyte and membrane before repeating the zero-DO verification process. For optical probes that read above 0.2 mg/l in zero-DO solution, replace the sensor cap if it is expired or perform a 2-point calibration if applicable. Some optical DO probes are capable of 2-point calibrations using a zero-DO solution and the air-saturated water method discussed in Section 3.2.2. Refer to the manufacturer's instruction manual for the appropriate 2-point calibration procedure. Ensure that the probe is thoroughly rinsed of zero-DO solution after verification or calibration to avoid measurement interferences caused by residual sodium sulfite.

3.3 Maintenance

Maintenance procedures vary depending on the technology utilized by each instrument and the manufacturer. The manufacturer's instruction manual should be consulted for instrument specific procedures. Following are some general guidelines for maintaining dissolved oxygen meters:

- Inspect probes for damage prior to use.
- For Clark cell probes, membranes and electrolyte solution should be changed prior to each study, when feasible.
- Battery voltages should be checked. For meters that will be deployed unattended, new or fully charged batteries should be used for each study.
- All calibration and maintenance procedures performed should be thoroughly documented.

COPY

3.4 Conducting Field Measurement of Dissolved Oxygen

Following are guidelines for conducting field measurements of dissolved oxygen:

- Except as described in specific operating procedures, dissolved oxygen measurements should if possible be conducted *in-situ*.
- When measuring DO at distinct points in the water column, the probe should be allowed to equilibrate at each location prior to recording the measurement.
- In water bodies with a great deal of flow, a weight may be attached to the probe guard or support cable to insure the probe is maintained at the proper depth.
- Insure that the measurement location is representative of conditions within the water body or reach. Avoid measurements directly below turbulent sections or still water unless these conditions represent most of the water body or reach.
- The DO meter should be capable of auto-correcting for specific conductivity/salinity or a separate instrument should be used to measure specific conductivity/salinity so that the final DO measurement(s) can be corrected.

3.5 Operational Verification

A post-calibration and post-operation instrument verification check should be performed using one of the techniques described in Sections 3.2.1 and 3.2.2 or 3.2.3 (for 2-point calibrations) to quantify potential instrument drift during use. A verification check will be performed after a calibration and at the end of all measurements.

It may be appropriate to verify the calibration of a DO meter periodically during the course of a day's measurements when conducting individual measurements. A DO probe may be re-calibrated throughout the day if drift is occurring. The verification DO concentration should be measured and recorded in the field logbook prior to any instrument adjustment. For long-term deployments a post-operation verification should be performed at the end of the deployment.

Verification is done by comparing a post-calibration or post-operation reading at 100% saturation conditions to a DO solubility table value at the ambient air/water temperature and barometric pressure. Post-calibration and post-operation readings should not exceed a maximum of ± 0.2 mg/l from the DO solubility table value. DO solubility tables can be accessed via the U.S. Geological Survey's DOTABLES software (USGS, 2013*b*) which are based on equations from Benson and Krause (1980; 1984).

1 General Information

1.1 Purpose

This document describes procedures, methods and considerations to be used and observed when conducting field Oxidation-Reduction Potential (ORP) measurements in aqueous environmental media, including groundwater, surface water and certain wastewater. The measurement of soil ORP is a non-standard measurement and procedures should be developed on a project-specific basis.

1.2 Scope/Application

This document describes procedures generic to all ORP measurement methods to be used by Science and Ecosystem Support Division (SESD) field personnel when collecting and handling samples in the field. On the occasion SESD personnel determine that any of the procedures described in this section are inappropriate, inadequate or impractical and that another procedure must be used to obtain an ORP measurement, the variant procedure will be documented in the field logbook, along with a description of the circumstances requiring its use. Mention of trade names or commercial products in this operating procedure does not constitute endorsement or recommendation for use.

1.3 Documentation/Verification

This procedure was prepared by persons deemed technically competent by SESD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the SESD local area network (LAN). The Document Control Coordinator (DCC) is responsible for ensuring the most recent version of the procedure is placed on the SESD LAN and for maintaining records of review conducted prior to its issuance.

1.5 General Considerations

1.5.1 Safety

Proper safety precautions must be observed when verifying or calibrating instruments for measurement of Oxidation-Reduction Potential. Refer to the SESD Safety, Health and Environmental Management Program Procedures and Policy Manual (most recent version) and any pertinent site-specific Health and Safety Plans (HASP) for guidelines on safety precautions. These guidelines should be used to complement the judgment of an experienced professional.

Reagents commonly used in the preparation of ORP calibration standards are toxic and require care when handling. When using this procedure, avoid exposure to these materials through the use of protective clothing, eye wear and gloves. Safety precautions when handling and preparing verification solutions should include gloves and eyewear to prevent dermal and eye contact, and a mask to avoid inhaling dust particles when handling dry materials. Vigorous flushing should be used if the reagents or solutions come in contact with skin or eyes. Following is specific information on commonly used solutions. The application of the solutions is described in detail in Section 3.1, Standard Solutions, of this procedure.

- Quinhydrone (CAS# 106-34-3) is a skin and respiratory irritant and is poisonous if ingested. Safety precautions when handling quinhydrone should include gloves to prevent dermal contact and a mask to avoid inhaling dust particles when mixing dry

COPY

material to prepare calibration standards. Vigorous flushing should be used if concentrated material comes in contact with skin or eyes.

- Zobell's solution is also an irritant and toxic if ingested. The same handling precautions apply when mixing and using Zobell's solution as when using quinhydrone. Zobell's reacts with acid to form harmful byproducts, including hydrocyanide gas.

- Light's solution contains ferro- and ferric-cyanide compounds in sulfuric acid. The components are toxic and burns are possible from contact with this solution.

- Potassium iodide solutions have lower toxicity than most calibration solution options. General ingestion, skin contact, and eye contact precautions apply.

Unused quinhydrone, Zobell's, Light's or other calibration reagents and solutions should be returned to SESD for disposal in accordance with the SESD Safety, Health, and Environmental Management Plan (SHEMP).

1.5.2 Records

Documentation of field activities is done in a bound logbook. All records, including a unique, traceable identifier for the instrument, should be entered according to the procedures outlined in the SESD Operating Procedure for Logbooks (SESDPROC-010, most recent version) and the SESD Operating Procedure for Equipment Inventory and Management, (SESDPROC-108, most recent version).

All field ORP measurements pertinent to the sampling event should be recorded in the field logbook for the event as outlined in the SESD Operating Procedure for Logbooks (SESDPROC-010, most recent version), or managed electronically with appropriate backups as described in SESD Operating Procedure for Control of Records (SESDPROC-002, most recent version).

1.5.3 Shipping

Shipped material shall conform to all U.S. Department of Transportation (DOT) rules of shipment found in Title 49 of the Code of Federal Regulations (49 CFR parts 171 to 179), and/or International Air Transportation Association (IATA) hazardous materials shipping requirements found in the current edition of IATA's Dangerous Goods Regulations.

All shipping documents, such as bills of lading, will be retained by the project leader and stored in a secure place.

COPY

2 Background

2.1 General

Oxidation is the process of liberating electrons or gaining oxygen. Examples of oxidation include conversion of elemental iron to rust, elemental sulfur to sulfate, and elemental hydrogen to water (Pankow 1991). Reduction is the process of gaining electrons resulting in the charge on some atomic unit in the species to be reduced. Oxidation-reduction potential (ORP) or redox potential (hereafter, referred to as redox) is a measure of the intensity or activity of an aqueous environment or soil to mediate reactions of important elements in biological systems (e.g., O, N, Mn, Fe, S, and C) and other metallic elements.

Considerable confusion arises on the use of the terms oxidation and reduction as they apply to the media under study. The following introduction reproduced from an online 'Wikipedia' article on the topic lucidly explains their relationship in ORP measurement:

> **Reduction potential** (also known as **redox potential**, **oxidation / reduction potential** or **ORP**) is the tendency of a chemical species to acquire electrons and thereby be reduced. Each species has its own intrinsic reduction potential; the more positive the potential, the greater the species' affinity for electrons and tendency to be reduced.
>
> In aqueous solutions, the reduction potential is the tendency of the solution to either gain or lose electrons when it is subject to change by introduction of a new species. A solution with a higher (more positive) reduction potential than the new species will have a tendency to gain electrons from the new species (i.e. to be reduced by oxidizing the new species) and a solution with a lower (more negative) reduction potential will have a tendency to lose electrons to the new species (i.e. to be oxidized by reducing the new species). Just as the transfer of hydrogen ions between chemical species determines the pH of an aqueous solution, the transfer of electrons between chemical species determines the reduction potential of an aqueous solution. Like pH, the reduction potential represents an intensity factor. It does not characterize the capacity of the system for oxidation or reduction, in much the same way that pH does not characterize the buffering capacity.

In short, a numerically positive redox potential or ORP represents an environment conducive to the oxidation of an introduced substance by reduction of the original media.

COPY

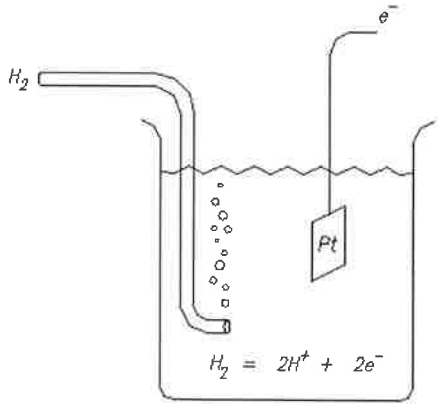
2.2 Instrumentation

ORP measurement systems are a practical implementation of electrochemical cells, which use metal electrodes in a solution to generate an electric current or voltage. If a platinum electrode is immersed in water with hydrogen bubbled into the solution, the H^2 is oxidized as follows:

$$H^2 = 2H^+ + 2e^-$$

In the electrochemical half-cell illustrated below in Fig.1, hydrogen gas oxidizes to hydrogen ions and free electrons, comprising an oxidation-reduction couple. This couple reaches an equilibrium state that maintains the reference potential of the electrode. The electric potential develops on the wire connected to the platinum electrode, but is difficult to measure in practice in the isolated half-cell. However, when used in a complete electrochemical cell, the cell illustrated is used as a reference to measure other half-cells against, and is called a Standard Hydrogen Electrode (SHE).

Figure 1

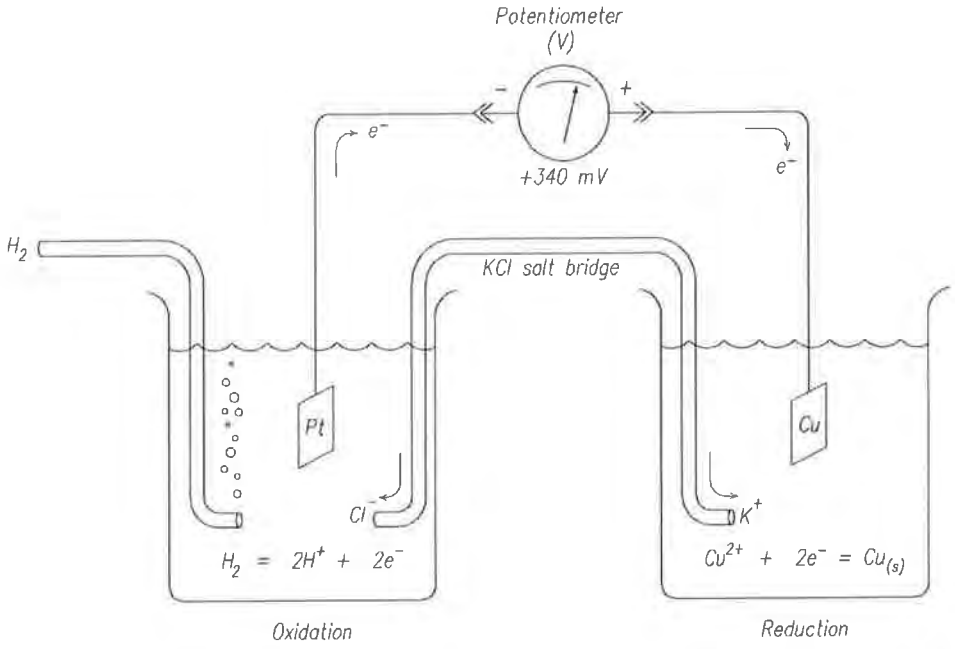


Hydrogen Half-Cell

If, as shown in Figure 2, a SHE is connected with a salt bridge to a second half-cell in which a reduction reaction is taking place, the electric potential between the two cells can be measured. In the case shown, the potential of the right cell will be +0.34 Volts in reference to the standard hydrogen electrode on the left. This would be represented as an Oxidation Reduction Potential (ORP) of +340mV on the hydrogen scale, or simply as Eh = +340mV.

COPY

Figure 2

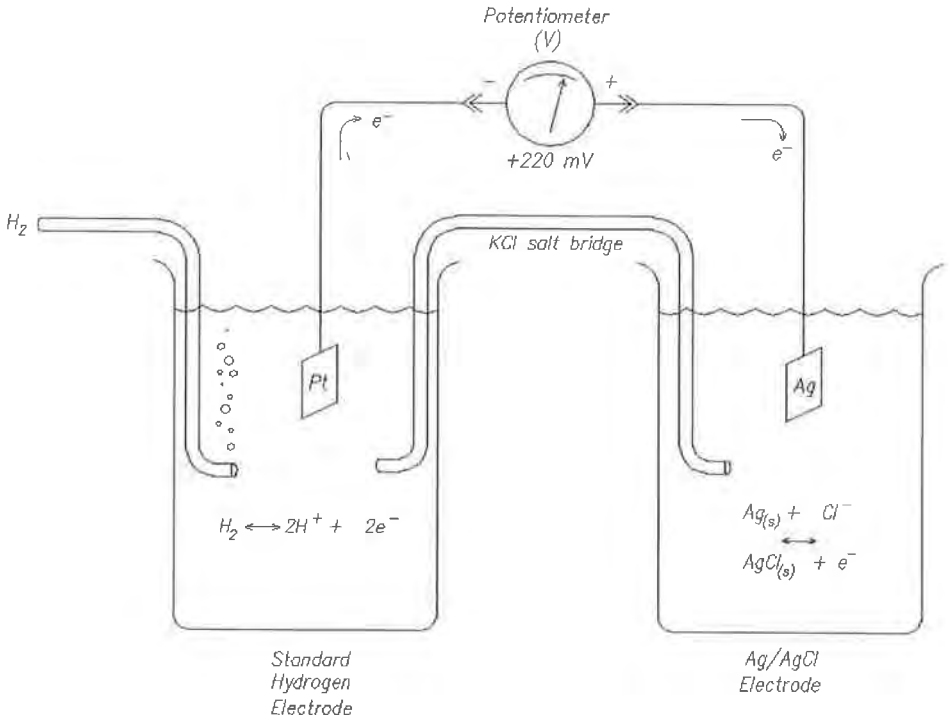


In field practice, the hydrogen electrode is difficult to reproduce. To conduct field measurements, a reference electrode is needed that is simple to maintain and will generate a potential that can be referenced to the standard hydrogen electrode. These requirements are met by the Saturated Calomel Electrode (SCE) and the Silver/Silver Chloride Electrode (SSCE - the SSCE is also commonly identified as an Ag/AgCl electrode). The SCE contains a small amount of elemental mercury, and while useful for certain applications, would rarely be used at SESD. The SSCE or Ag/AgCl electrode is generally used as the reference cell in SESD instrumentation.

In Figure 3 below, a SHE is connected to an Ag/AgCl electrode. In this example of an electrochemical cell, both cells reach an equilibrium potential. At that equilibrium state, the potential of the Ag/AgCl cell is 220mV more positive than the standard hydrogen electrode.

COPY

Figure 3



This half-cell potential of the Ag/AgCl electrode in reference to the SHE is used to convert measurements taken with an Ag/AgCl reference back to the hydrogen scale. While the laboratory Ag/AgCl half-cell shown has a potential of +220mV, practical reference cells have varying potentials based on temperature and filling solutions as shown in Table 1 below.

Table 1

Half-cell Potential of Ag/AgCl reference electrode

derived from USGS NFM, Table 6.5.2 (9/2005)

	Molarity of KCl filling solution			
T(°C)	3M	3.3M*	3.5M	Sat/4M
10	220	217	215	214
15	216	214	212	209
20	213	210	208	204
25	209	207	205	199
30	205	203	201	194

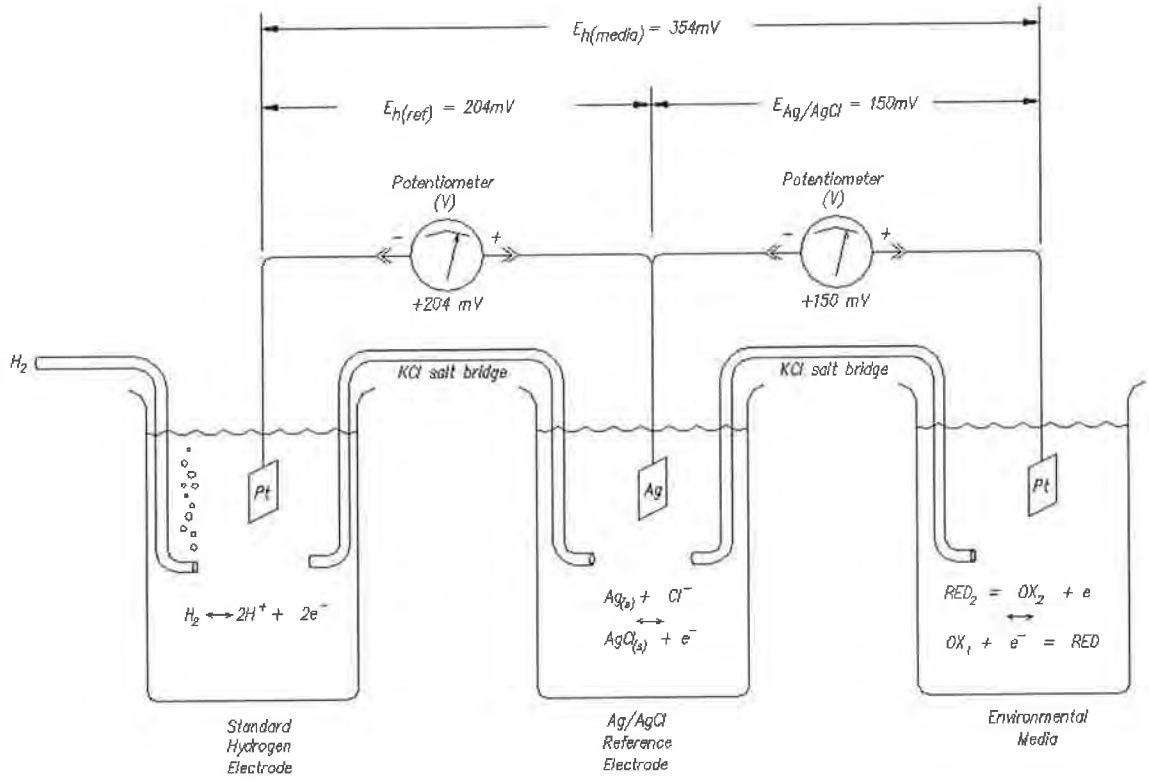
*interpolated value

COPY

Note: YSI sondes and Thermo electrodes typically use 4M KCl filling solutions. Eureka sondes typically use 3.3M KCl filling solutions.

In Figure 4, below, the relationship between a hydrogen electrode, a reference electrode, and a platinum sensing electrode in an arbitrary media is shown. In this case, the ORP of the media in reference to the silver/silver chloride electrode is 150mV. To obtain Eh, the potential of the reference electrode in relation to a hydrogen electrode is added to the potential of the sensing electrode in relation to the reference electrode. In practice, the potential of the reference electrode in relation to a hydrogen electrode is not measured, but obtained from Table 1 above.

Figure 4

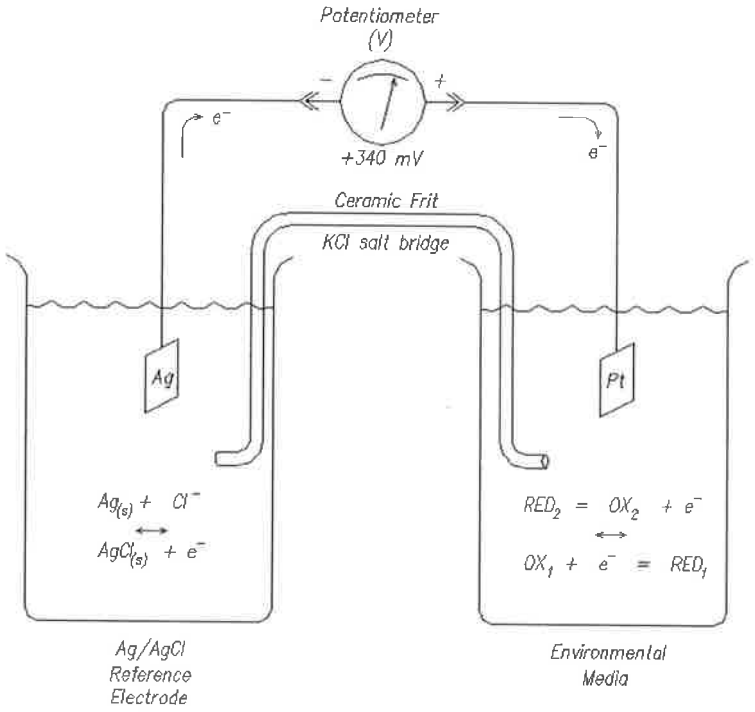


In Figure 5 below, a field instrument is represented as separate electrochemical cells. The

COPY

Ag/AgCl reference electrode uses a ceramic frit or other means to provide the essential salt bridge to the environmental media. The platinum sensing electrode is immersed in the environmental media and connected internally in the instrument to measure the potential (voltage) between the two electrodes.

Figure 5



In this illustration, the ORP is measured as 340 mV. This measurement is made in reference to the Ag/AgCl reference electrode and would be reported as such, or as $E_{Ag/AgCl}$ = 340mV.

In some cases it will be desirable to report the reading on the hydrogen scale, or Eh. To do so, the potential of the reference electrode against the SHE, obtained from Table 1, is added to $E_{Ag/AgCl}$. For our example:

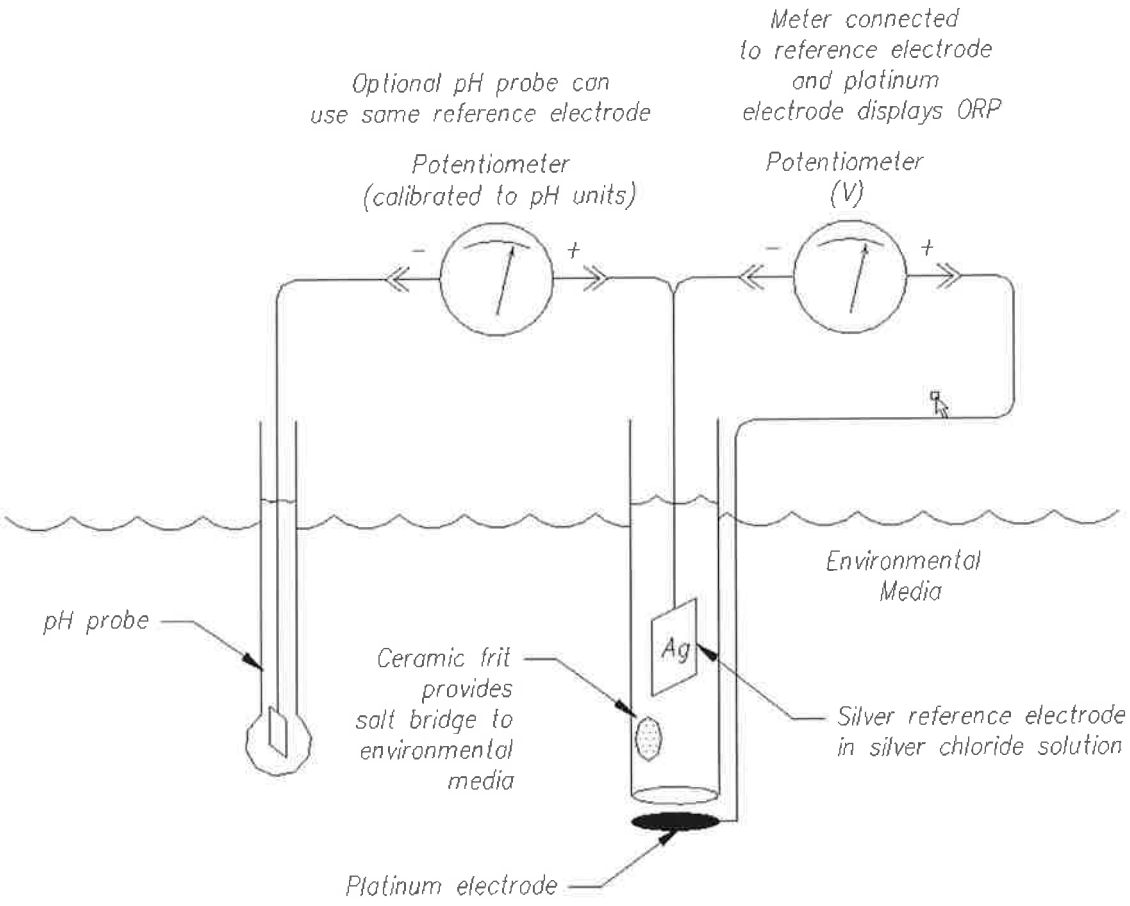
	340 mv	Measured ORP ($E_{Ag/AgCl}$) of sample
+	204 mV	Eh of Ag/AgCl electrode (ORP of Ag/AgCl electrode referenced to SHE)
	544 mV	Eh of sample

Both the +340 mV field reading and the adjusted +544 mV Eh can properly be referred to as ORP results. It is only through specifying the reference scale that the ambiguity can be eliminated.

COPY

In Figure 6, below, the theoretical cells shown above have been configured as a practical field instrument. The salt bridge is commonly provided by a ceramic frit connecting the environmental media to the reference electrode. In multi-parameter sondes, the pH probe commonly uses the same reference electrode as the ORP probe.

Figure 6



COPY

Redox Chemistry

In acid-base chemistry, the pH of a system is defined as the negative logarithm of the hydrogen ion activity (simplified in practice to the hydrogen ion concentration):

$$pH = -\log \{H^+\}$$

Similarly, Pankow (1991) described the negative logarithm of the electron activity (pe) as the master variable for describing the equilibrium position for all redox couples in a given system:

$$pe \ / \ - \log \{e^-\}$$

It can be shown (Pankow) that pe is related to Eh by

$$Eh = pe*(2.303*R*T)/F$$

Where:

R = gas constant = 8.314 J K^{-1} mol^{-1}
T = temperature, °K
F = Faraday constant = 96.485*10^3 C mol^{-1}

At 25°C (298°K) this simplifies to

$$E_H = pe * 0.05916$$

And

$$pe = E_H \ / 0.05916$$

According to Faulkner et al. (1989) redox is a quantitative measure of electron availability and is indicative of the intensity of oxidation or reduction in both chemical and biological systems. When based on a hydrogen scale, redox (E_H) is derived from the Nernst Equation (Stumm and Morgan 1981):

$$E_H = E_H^o + 2.3 \ H \ (R \ H \ T)/nF \ H \log (\vartheta_i \{ox\}^{ni}/\vartheta_j \{red\}^{nj})$$

Where:

E_H^o = potential of reference, mV
R = gas constant = 81.987 cal deg^{-1} $mole^{-1}$
T = temperature, °K
n = number of moles of electrons transferred
F = Faraday constant = 23.061 cal/mole-mv
{ox} and {red} = activity of the oxidants and reductants, respectively

COPY

2.4 Applications

When interpreted properly, redox combined with other conventional water quality parameters is useful in developing a more complete understanding of water chemistry. Several applications of redox are identified below:

1. Redox could be viewed as an extension of the oxygen scale. In this model, the DO probe spans the aerobic scale and the redox probe extends that scale to measure anaerobic conditions. Inferences to geochemistry and chemical speciation can be made from the oxidative state of the system. Application to metal sequestration, metal-iron, -sulfide, - methane complexation, and the subsequent bioaccumulation potential is possible.
2. Redox can be used to identify anaerobiosis at or near the water column and sediment interface in streams, lakes, and estuaries.
3. Redox may be useful in determination of stream jurisdiction and wetland delineation in that it can indicate conditions of soil saturation.
4. Based on redox, a pe (or EH) vs. pH stability diagram can be developed to aid in nutrient exchange studies including the timing, release, and partitioning of important water and sediment quality pollutants such as nitrogen and phosphorus species. Most importantly, redox can be used to address error associated with chamber-effect during closed chamber measurements of the water-sediment interface. Redox probes placed inside the contact chamber and inserted approximately ten centimeters into the underlying sediment can be used to monitor changes in sediment redox caused by the chamber, and steps can be taken to reduce chamber-effect.
5. Redox may be useful in establishing water and sediment quality standards applicable to wetlands.
6. Redox is used to assess the potential of a groundwater system to support various in situ reactions with contaminants, such as reductive dechlorination of chlorinated solvents.
7. Redox can provide a useful indicator of conditions that might compromise the performance of Clark-type dissolved oxygen (DO) probes. In general, anaerobic conditions occur at a redox range of +150 mV to +300 mV (pH-dependent and adjusted to hydrogen reference electrode). When redox drops below this level, DO measurements as determined with a Clarke-type probe are highly suspect as the semi-permeable membrane does not discriminate between partial O_2 and sulfides. Consequently, the meter may be reading sulfides.

COPY

2.5 Limitations

In most environmental media, redox reactions will not reach equilibrium due to low concentrations or multiple redox species. Consequently, redox measurements can generally be considered semi-quantitative in environmental media, unless certain conditions exist.

The USGS in the Interferences and Limitations Section 6.5.3A of their National Field Manual succinctly describe some of the issues encountered in the application of ORP measurements. This section is reproduced here, unedited:

> 6.5.3.A INTERFERENCES AND LIMITATIONS
>
> *Measurements should not be carried out without an awareness of the interferences and limitations inherent in the method.*
>
> - *Organic matter and sulfide may cause contamination of the electrode surface, salt bridge, or internal electrolyte, which can cause drift or erratic performance when reference electrodes are used (American Public Health Association and others, 2001).*
>
> - *Hydrogen sulfide can produce a coating on the platinum electrode that interferes with the measurement if the electrode is left in sulfide-rich water for several hours (Whitfield, 1974; Sato, 1960).*
>
> - *The platinum single and combination redox electrodes may yield unstable readings in solutions containing chromium, uranium, vanadium, or titanium ions and other ions that are stronger reducing agents than hydrogen or platinum (Orion Research Instruction Manual, written commun., 1991).*
>
> - *Do not insert redox electrodes into iron-rich waters directly after the electrode(s) contact ZoBell's. An insoluble blue precipitate coats the electrode surface because of an immediate reaction between ferro- and ferricyanide ions in ZoBell's with ferrous and ferric ions in the sample water, causing erratic readings.*
>
> *Many elements with more than one oxidation state do not exhibit reversible behavior at the platinum electrode surface and some systems will give mixed potentials, depending on the presence of several different couples (Barcelona and others, 1989; Bricker, 1982, p. 59–65; Stumm and Morgan, 1981, p. 490–495; Bricker, 1965, p. 65). Methane, bicarbonate, nitrogen gas, sulfate, and dissolved oxygen generally are not in equilibrium with platinum electrodes (Berner, 1981).*
>
> **TECHNICAL NOTE:**
>
> *Misconceptions regarding the analogy between Eh (pe) and pH as master variables and limitations on the interpretation of Eh measurements are explained in Hostettler (1984), Lindberg and Runnells (1984), Thorstenson (1984), and Berner (1981). To summarize:*

COPY

(1) Hydrated electrons do not exist in meaningful concentrations in most aqueous systems—in contrast, pH represents real activities of hydrated protons. Eh may be expressed as pe (the negative logarithm of the electron activity), but conversion to pe offers no advantage when dealing with measured potentials.

(2) Do not assume that redox species coexist in equilibrium. Many situations have been documented in which dissolved oxygen coexists with hydrogen sulfide, methane, and ferrous iron.

- *The practicality of Eh measurements is limited to iron in acidic mine waters and sulfide in waters undergoing sulfate reduction.*

- *Other redox species are not sufficiently electroactive to establish an equilibrium potential at the surface of the conducting electrode.*

(3) A single redox potential cannot be assigned to a disequilibrium system, nor can it be assigned to a water sample without specifying the particular redox species to which it refers. Different redox elements (iron, manganese, sulfur, selenium, arsenic) tend not to reach overall equilibrium in most natural water systems; therefore, a single Eh measurement generally does not represent the system.

COPY

3 Methodology

3.1 Standard Solutions

Care should be taken not to contaminate standards and samples and to verify the expiration date of all standards prior to use. All meters should be verified or calibrated according to the manufacturer's procedures.

Standard solutions for calibration and verification should be selected to meet project requirements. SESD generally maintains a stock of Zobell's solution suitable for most projects. The characteristics and use of the common standard solutions are described below.

- Zobell's solution contains potassium ferri- and ferro- cyanide compounds. The solution is available as prepared solutions or premeasured reagents for mixing by the user. Zobell's has moderate toxicity but will react with acid to form harmful byproducts, including hydrocyanide gas. It has a shelf life ranging from several days to several months depending on the manufacturer. Stock and working solutions of Zobell's should be stored in dark bottles due to its light sensitivity.

- Quinhydrone solutions are mixed at the time of use by adding quinhydrone to pH 4 or pH 7 buffers. At 25°C, the E_h of quinhydrone pH 4 and pH 7 verification solutions are 462mV and 285mV respectively. An advantage of quinhydrone solutions is that they offer a span of calibration points that may be appropriate for particular applications. Quinhydrone is a lightly 'poised' solution in that it offers less driving force towards the calibration point: a compromised instrument is more likely to be revealed in a quinhydrone calibration. A quinhydrone calibration/verification solution is created by adding 10g of quinhydrone to 1L of pH 4 or pH 7 buffer solution (ASTM D1498). The solutions are mixed on a magnetic mixing plate for a minimum of 15 minutes to create a saturated solution with undissolved crystals remaining. Quinhydrone solutions are usable for 8 hrs from the time of mixing.

- Light's solution consists of ferrous and ferric ammonium sulphate in sulphuric acid. The solution would rarely be used at SESD due to its high acidity and associated handling difficulty. Spent solutions with a pH<2 would be regulated as a hazardous waste. Light's is a highly poised solution that may allow a marginally functioning electrode to pass calibration.

- A prepared potassium iodide solution is available which has low toxicity and a long shelf life. The solution may stain clothing or surfaces if spilled.

COPY

3.2 Verification and Calibration

ORP instruments may be **verified** or **calibrated**, depending on the application. The approach chosen should be selected based on project needs and information presented in Section 2.4., Limitations. Standard laboratory practice in making ORP measurements is to **verify** the accuracy of the instrument prior to use, and this practice should be followed when true quantitative results are required. In a **verification,** the instrument in its direct-reading mode is checked against a standard solution in a pass/no-pass test, and no corrections are applied to subsequent measurements. In most applications, the ORP information is used semi-quantitatively and for these applications, the instruments may be **calibrated** to the standard solutions. In an instrument **calibration**, the instrument probe is placed in the standard solution and the difference between the standard measurement and the known ORP value of the standard is used by the instrument to make adjustments to the subsequent measurements.

In **verification** of an ORP instrument, the instrument is set to absolute mV reading mode or the internal calibration offset is zeroed out. The instrument probe should then be placed in the standard solution and the reading verified to fall within +/-10mV of the predicted reading for the standard. Instruments with single-purpose electrodes are most suitable for this approach. If the instrument fails the verification, standard solution quality should be considered and instrument maintenance performed per the manufacturer's procedures.

In most SESD field practice, the end data use is semi-quantitative. In this case, the instruments can be **calibrated** to standard solutions appropriate for the project using the manufacturer's recommended procedure. One minute after the calibration, the instrument should display a stable reading within +/-10mV of the predicted reading. An instrument failing this test should be recalibrated to determine if the problem is inadequate equilibration time. In the event of continued instrument failure, aging or contamination of the standard solution should be considered. Subsequently the electrode should be serviced according to the manufacturer's procedures. Common service procedures include cleaning the platinum electrode with mild abrasives or acids and refilling or replacing the reference electrode.

Prior to a mobilization, all ORP instruments will be checked for proper operation and verified or calibrated against standard solutions. During the field mobilization, each instrument will be calibrated or verified prior to, and verified after, each day's use or deployment.

Even though it is not necessary to re-calibrate ORP instrument at regular intervals during the day, it may be appropriate to occasionally perform operational checks to determine if site conditions, such as an extreme temperature change or submersion of a filling solution port have impacted the instrument's performance. If an operational check is warranted, the field operator should follow the appropriate verification/calibration steps as described above.

The predicted ORP values of standard solutions will be obtained from the manufacturer of prepared solutions, literature, or appropriate values listed in this procedure. Care is in order, as the predicted ORP value is specific for the type of reference electrode used by the probe (either Ag/AgCl or calomel) and the molarity of the filling solution in the reference electrode. To use the

COPY

solution with another electrode or filling solution, the expected ORP readings for the solution should be converted to Eh for the probes intended for the solution as per the Reporting section of this procedure. Then a table can be compiled for the electrode in use by subtracting the $E_{h,ref}$ for the electrode and filling solution in use. This will be done at the Field Equipment Center (FEC) for the solutions stocked.

Verification solutions should be managed per the manufacturer's directions regarding storage and handling. After instrument verification or calibration, the solution cannot be returned to the stock solution container, although a separate container of working solution can be maintained.

Spent solutions and working solutions should be returned from the field to the SESD laboratory for proper disposal by the SHEMP, or handled as directed by the SHEMP. Properly handled stock solutions may be returned to the FEC for use at that facility.

3.3 Measurement

ORP measurements should be conducted in a fashion that prevents the addition or loss of any potential oxidants or reductants. Results could be compromised by exposing the sample to air or allowing H_2S to off-gas from anoxic samples. Like dissolved oxygen measurements, ORP measurements should be conducted in situ or by using a flow-through cell evacuated of air (see the SESD Operating Procedure for Field Measurement of Dissolved Oxygen (SESDPROC-106, most recent version). Good results are commonly obtained with the use of an overtopping cell where the environmental media is pumped into the bottom of a narrow cup (generally field fabricated from a sample container) containing the instrument sensors. The sensors are continually flushed with fresh media as the cup is allowed to overflow. Caution should be exercised at very low flow rates where the media in the cup could potentially re-oxygenate.

When using multi-parameter probes for ORP measurements, the general guidelines for probe deployment described in the SESD Operating Procedure for Field Measurement of Dissolved Oxygen (SESDPROC-106, most recent version) and the SESD Operating Procedure for In situ Water Quality Monitoring (SESDPROC-111, most recent version) apply.

ORP probes must be operated and maintained in accordance with the manufacturer's instructions. Reference electrodes in multi-parameter probes may require regular filling or replacement. Single parameter ORP electrodes may require regular filling and operation in an upright position to assure that proper salt bridge flow is maintained. Platinum electrode surfaces are easily contaminated and polishing or cleaning of the electrodes should be performed as recommended by the manufacturer.

Measurements in field logbooks should be recorded to the nearest mV. The type of reference electrode in use and its filling solution should be recorded in at least one logbook as part of the field project records.

ORP is a temperature sensitive measurement, but ORP instruments are not temperature compensated. Consequently, the media temperature should always be recorded at the same time

COPY

as the ORP is recorded. Likewise, as ORP is often pH dependent, pH should also be recorded at the time of ORP measurement.

3.4 Reporting

In the absence of a specified reference scale, ORP data has no meaning. Therefore, the reference scale used should always be specified in reporting or discussing the ORP data. ORP measurements converted to a hydrogen scale can be reported as "E_h". Data reported as the direct field measurement without correction might be described as "ORP referenced to Ag/AgCl electrode" or "$E_{Ag/AgCl}$". The expectations of the data user should be ascertained or the measurements should be reported in both systems.

To apply corrections to obtain E_h from the direct field measurement, the known half-cell potential of the reference electrode is added to the recorded field ORP value:

$$E_{h,sample} = ORP_{sample} + \text{half-cell potential of reference electrode}$$

The following table, reproduced from Section 2.2, presents the half-cell potential of a silver/silver chloride reference electrode at various temperatures and with various molarities of KCl filling solutions.

Table 1

Half-cell Potential of Ag/AgCl reference electrode

derived from USGS NFM, Table 6.5.2 (9/2005)

	Molarity of KCl filling solution			
T(°C)	3M	3.3M*	3.5M	Sat/4M
10	220	217	215	214
15	216	214	212	209
20	213	210	208	204
25	209	207	205	199
30	205	203	201	194
35	202	199	197	189
40	198	195	193	184

*interpolated value

Note: YSI sondes and Thermo electrodes typically use 4M KCl filling solutions. Eureka sondes typically use 3.3M KCl filling solutions

Example:

A multi-parameter probe with a silver/silver chloride reference electrode and 4M KCl filling solution is used to record a stream ORP measurement of 146mV. The stream temperature is recorded as 15°C.

COPY

From the above table, the half-cell potential of an Ag/AgCl reference electrode filled with 4M KCl is 209mV at 15°C. Then:

$$E_{h,sample} = ORP_{Ag/AgCl,sample} + \text{half-cell potential of Ag/AgCl reference electrode}$$

$$E_{h,sample} = 146mV + 209mV$$

$$E_{h,sample} = 355mV$$

As noted in Section 3.3, Measurement, ORP measurements are sensitive to temperature, and may be sensitive to pH. As the instruments do not compensate for these parameters, ORP data should always be reported with the temperature and pH of the media at the time of measurement.

Final reporting values of Eh or ORP should be rounded to the nearest 10mV. The following spreadsheet formula can perform the rounding of an interim result located in spreadsheet cell 'A1':

=INT(A1/10+0.5)*10

EXHIBIT P-4

FIELD EQUIPMENT CLEANING AND DECONTAMINATION

(LSASDPROC-205-R4)

Region 4 U.S. Environmental Protection Agency Laboratory Services and Applied Science Division Athens, Georgia	
Operating Procedure	
Title: Field Equipment Cleaning and Decontamination	ID: LSASDPROC-205-R4
Issuing Authority: LSASD Field Branch Chief	
Effective Date: June 22, 2020	Review Due Date: June 22, 2023

Purpose

This procedure is to be used by Region 4 Laboratory Services and Applied Science Division staff . This document describes general and specific procedures, methods and considerations to be used and observed when cleaning and decontaminating sampling equipment during the course of field investigations. This procedure is to be used by all Region 4 Laboratory Services and Applied Science Division (LSASD) staff.

Scope/Application

The procedures contained in this document are to be followed when field cleaning sampling equipment, for both re-use in the field, as well as used equipment being returned to the Field Equipment Center (FEC). On the occasion that LSASD field investigators determine that any of the procedures described in this section are either inappropriate, inadequate or impractical and that other procedures must be used to clean or decontaminate sampling equipment at a particular site, the variant procedure will be documented in the field logbook, along with a description of the circumstances requiring its use. Mention of trade names or commercial products in this operating procedure does not constitute endorsement or recommendation for use.

Uncontrolled When Printed

1 General Information

1.1 Documentation/Verification

This procedure was prepared by persons deemed technically competent by LSASD management, based on their knowledge, skills and abilities and have been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the LSASD Local Area Network (LAN). The Document Control Coordinator (DCC) is responsible for ensuring the most recent version of the procedure is placed on LAN and for maintaining records of review conducted prior to its issuance.

1.2 Definitions

- Decontamination: The process of cleaning dirty sampling equipment to the degree to which it can be re-used, with appropriate QA/QC, in the field.

- Deionized water: Tap water that has been treated by passing through a standard deionizing resin column. At a minimum, the finished water should contain no detectable heavy metals or other inorganic compounds (i.e., at or above analytical detection limits) as defined by a standard inductively coupled Argon Plasma Spectrophotometer (ICP) (or equivalent) scan. Deionized water obtained by other methods is acceptable, as long as it meets the above analytical criteria. Organic-free water may be substituted for deionized water.

- Detergent shall be a standard brand of phosphate-free laboratory detergent such as Liquinox® or Luminox®. Liquinox® is a traditional anionic laboratory detergent and is used for general cleaning and where there is concern for the stability of the cleaned items in harsher cleaners. Luminox® is a specialized detergent with the capability of removing oils and organic contamination. It is used in lieu of a solvent rinse step in cleaning of equipment for trace contaminant sampling. Where not specified in these procedures, either detergent is acceptable.

- Drilling Equipment: All power equipment used to collect surface and sub-surface soil samples or install wells. For purposes of this procedure, direct push is also included in this definition.

- Field Cleaning: The process of cleaning dirty sampling equipment such that it can be returned to the FEC in a condition that will minimize the risk of transfer of contaminants from a site.

- Organic-free water: Tap water that has been treated with activated carbon and deionizing units. At a minimum, the finished water must meet the analytical criteria of deionized water and it should contain no detectable pesticides, herbicides, or extractable organic compounds, and no volatile organic compounds above minimum detectable levels as determined by the Region 4 laboratory for a given set of analyses. Organic-free water obtained by other methods is acceptable, as long as it meets the above analytical criteria.

- Tap water: Water from any potable water supply. Deionized water or organic-free water may be substituted for tap water.

Uncontrolled When Printed

1.3 General Precautions

1.3.1 Safety

Proper safety precautions must be observed when field cleaning or decontaminating dirty sampling equipment. Refer to the LSASD Safety, Health and Environmental Management Program (SHEMP) Procedures and Policy Manual and any pertinent site-specific Health and Safety Plans (HASPs) for guidelines on safety precautions. These guidelines, however, should only be used to complement the judgment of an experienced professional. Address chemicals that pose specific toxicity or safety concerns and follow any other relevant requirements, as appropriate. At a minimum, the following precautions should be taken in the field during these cleaning operations:

- When conducting field cleaning or decontamination using laboratory detergent, safety glasses with splash shields or goggles, and latex gloves will be worn.
- No eating, smoking, drinking, chewing, or any hand to mouth contact should be permitted during cleaning operations.

1.3.2 Procedural Precaution

Prior to mobilization to a site, the expected types of contamination should be evaluated to determine if the field cleaning and decontamination activities will generate rinses and other waste waters that might be considered RCRA hazardous waste or may require special handling.

2 Introduction to Field Equipment Cleaning and Decontamination

2.1 General

The procedures outlined in this document are intended for use by field investigators for cleaning and decontaminating sampling and other equipment in the field. These procedures should be followed in order that equipment is returned to the FEC in a condition that will minimize the risk of transfer of contaminants from a site.

Sampling and field equipment cleaned in accordance with these procedures must meet the minimum requirements for the Data Quality Objectives (DQOs) of the study or investigation. If deviations from these procedures need to be made during the course of the field investigation, they will be documented in the field logbook along with a description of the circumstances requiring the use of the variant procedure.

Cleaning procedures for use at the Field Equipment Center (FEC) are found in LSASD Operating Procedure for Equipment Cleaning and Decontamination at the FEC (LSASDPROC-206).

2.2 Handling Practices and Containers for Cleaning Solutions

Improperly handled cleaning solutions may easily become contaminated. Storage and application containers must be constructed of the proper materials to ensure their integrity. Following are acceptable materials used for containing the specified cleaning solutions:

Uncontrolled When Printed

- Detergent must be kept in clean plastic, metal, or glass containers until used. It should be poured directly from the container during use.

- Tap water may be kept in tanks, hand pressure sprayers, squeeze bottles, or applied directly from a hose.

- Deionized water must be stored in clean, glass or plastic containers that can be closed for transport. It can be applied from plastic squeeze bottles.

- Organic-free water must be stored in clean glass or Teflon® containers prior to use. It may be applied using Teflon® squeeze bottles, or with the portable system.

2.3 Disposal of Cleaning Solutions

Procedures for the safe handling and disposition of investigation derived waste (IDW); including used wash water and rinse water are in LSASD Operating Procedure for Management of Investigation Derived Waste (LSASDPROC-202).

2.4 Sample Collection Equipment Contaminated with Concentrated Materials

Equipment used to collect samples of concentrated materials from investigation sites must be field cleaned before returning from the study. At a minimum, this should consist of washing with detergent and rinsing with tap water. When the above procedure cannot be followed, the following options are acceptable:

- Leave with facility for proper disposal;

- If possible, containerize, seal, and secure the equipment and leave on-site for later disposal;

- Containerize, bag, or seal the equipment so that no odor is detected and return to the Field Equipment Center.

It is the project leader's responsibility to evaluate the nature of the sampled material and determine the most appropriate cleaning procedures for the equipment used to sample that material.

2.5 Sample Collection Equipment Contaminated with Environmental Media

Equipment used to collect samples of environmental media from investigation sites should be field cleaned before returning from the study. Based on the condition of the sampling equipment, one or more of the following options must be used for field cleaning:

- Wipe the equipment clean;

- Water-rinse the equipment;

- Wash the equipment in detergent and water followed by a tap water rinse.

- For grossly contaminated equipment, the procedures set forth in Section 2.4 must be followed.

Uncontrolled When Printed

Under extenuating circumstances such as facility limitations, regulatory limitations, or during residential sampling investigations where field cleaning operations are not feasible, equipment can be containerized, bagged or sealed so that no odor is detected and returned to the FEC without being field cleaned. If possible, FEC personnel should be notified that equipment will be returned without being field cleaned. It is the project leader's responsibility to evaluate the nature of the sampled material and determine the most appropriate cleaning procedures for the equipment used to sample that material.

2.6 Handling of Decontaminated Equipment

After decontamination, equipment should be handled only by personnel wearing clean gloves to prevent re-contamination. In addition, the equipment should be moved away (preferably upwind) from the decontamination area to prevent re-contamination. If the equipment is not to be immediately re-used, it should be covered with plastic sheeting or wrapped in aluminum foil to prevent re-contamination. The area where the equipment is kept prior to re-use must be free of contaminants.

3 Field Equipment Decontamination Procedures

3.1 General

Sufficient equipment should be transported to the field so that an entire study can be conducted without the need for decontamination. When equipment must be decontaminated in the field, the following procedures are to be utilized.

Note: Equipment utilized for PFAS sampling will not cleaned in the field.

3.2 Specifications for Decontamination Pads

Decontamination pads constructed for field cleaning of sampling and drilling equipment should meet the following minimum specifications:

- The pad should be constructed in an area known or believed to be free of surface contamination.
- The pad should not leak.
- If possible, the pad should be constructed on a level, paved surface and should facilitate the removal of wastewater. This may be accomplished by either constructing the pad with one corner lower than the rest, or by creating a sump or pit in one corner or along one side. Any sump or pit should also be lined.
- Sawhorses or racks constructed to hold equipment while being cleaned should be high enough above ground to prevent equipment from being splashed.
- Water should be removed from the decontamination pad frequently.
- A temporary pad should be lined with a water impermeable material with no seams within the pad. This material should be either easily replaced (disposable) or repairable.

Uncontrolled When Printed

At the completion of site activities, the decontamination pad should be deactivated. The pit or sump should be backfilled with the appropriate material designated by the site project leader, but only after all waste/rinse water has been pumped into containers for disposal. See LSASD Operating Procedure for Management of Investigation Derived Waste (LSASDPROC-202) for proper handling and disposal of these materials. If the decontamination pad has leaked excessively, soil sampling may be required.

3.3 "Classical Parameter" Sampling Equipment

"Classical Parameters" are analyses such as oxygen demand, nutrients, certain inorganic compounds, sulfide, flow measurements, etc. For routine operations involving classical parameter analyses, water quality sampling equipment such as Kemmerers, buckets, dissolved oxygen dunkers, dredges, etc., may be cleaned with the sample water or tap water between sampling locations as appropriate.

Flow measuring equipment such as weirs, staff gages, velocity meters, and other stream gauging equipment may be cleaned with tap water between measuring locations, if necessary.

Note: The procedures described in Section 3.3 are not to be used for cleaning field equipment to be used for the collection of samples undergoing trace organic or inorganic constituent analyses.

3.4 Sampling Equipment used for the Collection of Trace Organic and Inorganic Compounds

For samples undergoing trace organic or inorganic constituent analyses, the following procedures are to be used for all sampling equipment or components of equipment that come in contact with the sample:

3.4.1 Standard LSASD Method

- An optional Liquinox® detergent wash step may be useful to remove gross dirt and soil.
- Clean with tap water and Luminox® detergent using a brush, if necessary, to remove particulate matter and surface films.
- Rinse thoroughly with tap water.
- Rinse thoroughly with organic-free water and place on a clean foil-wrapped surface to air-dry.
- Wrap the dry equipment with aluminum foil or bag in clean plastic. If the equipment is to be stored overnight before it is wrapped in foil, it should be covered and secured with clean, unused plastic sheeting.

3.4.2 Alternative Solvent Rinse Method

The historical solvent rinse method of cleaning equipment for trace contaminant sampling remains an acceptable method.

- Clean with tap water and Liquinox® detergent using a brush, if necessary, to remove particulate matter and surface films. Equipment may be steam cleaned (Liquinox® detergent and high-pressure hot water) as an alternative to brushing. Sampling equipment that is steam cleaned should be placed on racks or saw horses at least two feet above the floor of the decontamination pad. PVC or plastic items should not be steam cleaned.

- Rinse thoroughly with tap water.

Uncontrolled When Printed

- Rinse thoroughly with deionized water.
- Rinse with an appropriate solvent (generally isopropanol).
- Rinse with organic-free water and place on a clean foil-wrapped surface to air-dry.
- Wrap the dry equipment with aluminum foil or plastic. If the equipment is to be stored overnight before it is wrapped, it should be covered and secured with clean, unused plastic sheeting.

3.5 Well Sounders or Tapes

The following procedures are recommended for decontaminating well sounders (water level indicators) and tapes. Unless conditions warrant, it is only necessary to decontaminate the wetted portion of the sounder or tape.

- Wash with Liquinox® detergent and tap water.
- Rinse with tap water.
- Rinse with deionized water.

3.6 Redi-Flo2® Pump

CAUTION – Do not wet the controller. Always disconnect power from the pump when handling the pump body.

The Redi-Flo2® pump and any associated connected hardware (e.g., check valve) should be decontaminated between each monitoring well. The following procedures are required, depending on whether the pump is used solely for purging or used for purging and sampling.

3.6.1 Purge Only (Pump and Wetted Portion of Tubing or Hose)

- Disconnect power and wash exterior of pump and wetted portion of the power lead and tubing or hose with Liquinox® detergent and water solution.
- Rinse with tap water.
- Final rinse with deionized water.
- Place pump and reel in a clean plastic bag and keep tubing or hose contained in clean plastic or galvanized tub between uses.

3.6.2 Purge And Sample

Uncontrolled When Printed

Grundfos Redi-Flo2® pumps are extensively decontaminated and tested at the FEC to prevent contamination from being transmitted between sites. The relevant sections of LSASDPROC-206, *Field Equipment Cleaning and Decontamination at the FEC,* should be implemented in the field where a high risk of cross-contamination exists, such as where NAPL or high-concentration contaminants occur. In most cases, the abbreviated cleaning procedure described below will suffice, provided that sampling proceeds from least to most contaminated areas.

- Disconnect and discard the previously used sample tubing from the pump. Remove the check valve and tubing adapters and clean separately (See Section 3.6.3 for check valve). Wash the pump exterior with detergent and water.

- Prepare and fill three containers with decontamination solutions, consisting of Container #1, a tap water/detergent washing solution. Luminox® is commonly used. An additional pre-wash container of Liquinox® may be used; Container #2, a tap water rinsing solution; and Container #3, a deionized or organic-free water final rinsing solution. Choice of detergent and final rinsing solution for all steps in this procedure is dependent upon project objectives (analytes and compounds of interest). The containers should be large enough to hold the pump and one to two liters of solution. An array of 2' long 2" PVC pipes with bottom caps is a common arrangement. The solutions should be changed at least daily.

- Place the pump in Container #1. Turn the pump on and circulate the detergent and water solution through the pump and then turn the pump off.

- Place the pump in Container #2. Turn the pump on and circulate the tap water through the pump and then turn the pump off.

- Place the pump in Container #3. Turn the pump on and circulate deionized or organic-free water through the pump and then turn the pump off.

- Disconnect power and remove pump from Container #3. Rinse exterior and interior of pump with fresh deionized or organic-free water.

- Decontaminate the power lead by washing with detergent and water, followed by tap water and deionized water rinses. This step may be performed before washing the pump if desired.

- Reassemble check valve and tubing adapters to pump. ALWAYS use Teflon® tape to prevent galling of threads. Firm hand-tightening of fittings or light wrench torque is generally adequate.

- Place the pump and reel in a clean plastic bag.

3.6.3 Redi-Flo2® Ball Check Valve

- Remove the ball check valve from the pump head. Check for wear and/or corrosion, and replace as needed. During decontamination check for free-flow in forward direction and blocking of flow in reverse direction.

- Using a brush, scrub all components with detergent and tap water.

Uncontrolled When Printed

- Rinse with deionized water.
- Rethread the ball check valve to the Redi-Flo2® pump head.

3.7 Mega-Monsoon® and GeoSub® Electric Submersible Pump

As these pumps have lower velocities in the turbine section and are easier to disassemble in the field than Grundfos pumps, the outer pump housing should be removed to expose the impeller for cleaning prior to use and between each use when used as a sampling pump for trace contaminant sampling.

- Remove check valves and adapter fittings and clean separately.
- Remove the outer motor housing by holding the top of the pump head and unscrewing the outer housing from its O-ring sealed seat.
- Clean all pump components per the provisions of section 3.4. Use a small bottle brush for the pump head passages
- Wet the O-ring(s) on the pump head with organic-free water. Reassemble the outer pump housing to the pump head.
- Clean cable and reel per Section 3.4.
- Conduct final rinse of pump with organic-free water over pump and through pump turbine.

3.8 Bladder Pumps

Bladder pumps are presumed to be intended for use as low flow purge-and-sample pumps. The Geotech® bladder pump and Geoprobe Systems® mechanical bladder pump can be cleaned similarly.

- Discard any tubing returned with the pump.
- Completely disassemble the pump, being careful to note the initial position of and retain any springs and loose ball checks.
- Discard pump bladder.
- Clean all parts as per the standard cleaning procedure in Section 3.4.
- Install a new Teflon® bladder and reassemble pump.

3.9 Downhole Drilling Equipment

While LSASD does not currently operate drilling equipment, LSASD personnel do oversee and specify drilling operations. The following procedures are to be used for drilling activities involving the collection of soil samples for trace organic and inorganic constituent analyses and for the construction of monitoring wells to be used for the collection of groundwater samples for trace organic and inorganic constituent analyses.

3.9.1 Introduction

Uncontrolled When Printed

Cleaning and decontamination of all equipment should occur at a designated area (decontamination pad) on the site. The decontamination pad should meet the specifications of Section 3.2 of this procedure.

Tap water brought on the site for drilling and cleaning purposes should be contained in a pre-cleaned tank.

A steam cleaner and/or high pressure hot water washer capable of generating a pressure of at least 2500 PSI and producing hot water and/or steam, with a detergent compartment, should be obtained.

3.9.2 Preliminary Cleaning and Inspection

Drilling equipment should be clean of any contaminants that may have been transported from off-site to minimize the potential for cross-contamination. The drilling equipment should not serve as a source of contaminants. Associated drilling and decontamination equipment, well construction materials, and equipment handling procedures should meet these minimum specified criteria:

- All downhole augering, drilling, and sampling equipment should be sandblasted before use if painted, and/or there is a buildup of rust, hard or caked matter, etc., that cannot be removed by steam cleaning (detergent and high pressure hot water), or wire brushing. Sandblasting should be performed prior to arrival on site, or well away from the decontamination pad and areas to be sampled.

- Any portion of the drilling equipment that is over the borehole (kelly bar or mast, backhoe buckets, drilling platform, hoist or chain pulldowns, spindles, cathead, etc.) should be steam cleaned (detergent and high pressure hot water) and wire brushed (as needed) to remove all rust, soil, and other material which may have come from other sites before being brought on site.

- Printing and/or writing on well casing, tremie tubing, etc., should be removed before use. Emery cloth or sand paper can be used to remove the printing and/or writing. Most well material suppliers can provide materials without the printing and/or writing if specified when ordered. Items that cannot be cleaned are not acceptable and should be discarded.

- Equipment associated with the drilling and sampling activities should be inspected to insure that all oils, greases, hydraulic fluids, etc., have been removed, and all seals and gaskets are intact with no fluid leaks.

3.9.3 Drill Rig Field Cleaning Procedure

Any portion of the drill rig, backhoe, etc., that is over the borehole (kelly bar or mast, backhoe buckets, drilling platform, hoist or chain pulldowns, spindles, cathead, etc.) should be steam cleaned (detergent and high pressure hot water) between boreholes.

3.9.4 Field Decontamination Procedure for Drilling Equipment

Uncontrolled When Printed

The following is the standard procedure for field cleaning augers, drill stems, rods, tools, and associated equipment. This procedure does not apply to well casings, well screens, or split-spoon samplers used to obtain samples for chemical analyses, which should be decontaminated as outlined in Section 3.4 of this procedure.

- Wash with tap water and detergent, using a brush if necessary, to remove particulate matter and surface films. Steam cleaning (high pressure hot water with detergent) may be necessary to remove matter that is difficult to remove with the brush. Drilling equipment that is steam cleaned should be placed on racks or saw horses at least two feet above the floor of the decontamination pad. Hollow-stem augers, drill rods, etc., that are hollow or have holes that transmit water or drilling fluids, should be cleaned on the inside with vigorous brushing.

- Rinse thoroughly with tap water.

- Remove from the decontamination pad and cover with clean, unused plastic if not used immediately. If stored overnight, the plastic should be secured to ensure that it stays in place.

3.9.5 Field Decontamination Procedure for Direct Push Technology (DPT) Equipment

- Certain specific procedures for the decontamination of DPT tools are described in the various sampling procedures, but the following general guidelines apply:

- Prior to return to the Field Equipment Center, all threaded tool joints should be broken apart and the equipment cleaned per the provisions of *Section 2.5, Sample Collection Equipment Contaminated with Environmental Media* of this procedure.

- Equipment that contacts the sample media and is cleaned in the field for reuse should be cleaned per the provisions of *Section 3.4, Sampling Equipment used for the Collection of Trace Organic and Inorganic Compounds* of this procedure. This would include piston sampler points and shoes, screen point sampler screens and sheaths, and the drive rods when used for groundwater sampling.

- Equipment that does not directly contact the sample media and is cleaned in the field for reuse can generally be cleaned per the provisions of Section *3.7.4, Field Decontamination Procedure for Drilling Equipment* of this procedure.

- Stainless steel SP15/16 well screens require special care as the narrow slots are difficult to clean under even controlled circumstances and galvanic corrosion can release chrome from the screen surface. As soon as possible after retrieval, the screen slots should be sprayed from the outside to break loose as much material as possible before it can dry in place. To prevent galvanic corrosion, the screens must be segregated from the sampler sheaths, drive rods, and other carbon steel during return transport from the field.

Uncontrolled When Printed

3.10 Rental Pumps

Completing a groundwater sampling project may require the use of rental pumps. Rental pumps are acceptable where they are of suitable stainless steel and Teflon® construction. These pumps should be cleaned prior to use using the procedures specified herein and a rinse-blank collected prior to use.

1.0 INTRODUCTION

Cavenham Forest Industries LLC (CFI) owns a site in Mobile, Alabama, that formerly produced treated wood products using the preservatives creosote and pentachlorophenol. The plant ceased operation in 1981 and the hazardous waste management units at the site were closed in accordance with closure plans approved by the Alabama Department of Environmental Management (ADEM). The location of the site relative to the city of Mobile is shown in Figure 1. Figure 2 is the current site plan. Presented herein is a Corrective Action Plan (CAP) designed to reduce groundwater migration potential and contamination at the site, to levels that do not pose a potential risk to human health or the environment.

This report provides an update to the Corrective Action Plan (CAP) for the site as part of the RCRA Post Closure Permit renewal. The proposed changes include the following items:

- Conversion of two (2) air sparging wells (AS-3 and AS-4) into recovery wells.
- Cessation of the air sparging technology, including plugging and abandonment of all air sparging wells.
- Decommission and removal of twelve (12) recovery wells.
- Restore or reinstall one (1) recovery well that was found to be silted in.

1.1 BACKGROUND

Cavenham obtained ownership of the Mobile facility from Crown Zellerbach Corporation in 1986. Crown Zellerbach acquired the property from Gulfport Creosoting Company in 1972. Preservative treatment of wood products has been the only manufacturing activity at the site. Wood treating operations began at the site in 1938 and ceased in November, 1981.

While the facility was actively manufacturing treated wood products, it generated and managed a listed RCRA hazardous waste K001 (40 CFR part 261). This waste was managed in four (4) RCRA hazardous management units, the Vacuum Ponds, the Sand Filtration Beds, the Aeration Pond, and the Container Storage Area. These units were collectively closed as a single landfill under an approved closure plan. ADEM issued a Certification of Closure to Cavenham on April 8, 1991.

Corrective Action Plans (CAP) have previously been developed for this site. This CAP has been prepared to update and supplement those previous plans. This present addendum of the CAP incorporates additional information gained from the installation of the post-closure groundwater monitoring and recovery well system (Cavenham, 1989 and Post-

Closure Permit, February, 1991), a phase of assessment activities conducted during the winter of 1991 and spring of 1992, and data obtained through corrective action monitoring that is ongoing at the site. Table 1 incudes the construction details for each of the site's wells.

1.2 OBJECTIVE

The objective of this CAP addendum is to optimize the remedial measures to contain and reduce groundwater contamination to concentrations that do not pose a potential risk to human health and the environment in a cost-effective manner. A Closure Plan has been implemented that partially satisfies these objectives (Cavenham, 1987a). The specific objectives of this addendum are as follows:

- Hydraulically contain and recover groundwater contamination that is outside the closed RCRA landfill in the Upper Aquifer.
- Hydraulically contain and recover groundwater contamination that is beneath and downgradient from the closed RCRA landfill in the Lower Aquifer.
- Hydraulically contain and recover groundwater within the closed RCRA landfill, thus reducing the magnitude of the contamination contained within the closed RCRA landfill (Closure Area), and mitigating further impacts from this source.

These objectives will remain unchanged until such time as the potential risk to human health and the environment is diminished or reduced to such a level that an alternative long term management strategy is recommended by CFI and approved by ADEM. Routine evaluations of the long-term management strategy are ongoing and will determine the need for continued corrective action at the current level of effort.

2.0 HYDROLOGY

The site is directly underlain by two water-bearing zones that are referred to as the Upper Aquifer and the Lower Aquifer. These aquifers are separate hydrogeological units throughout most of the southern portion of the site, however, they are contiguous units in the northern portion. The hydrogeology of each is summarized below. The reader is referred to Cavenham' s Groundwater Quality Assessment (Geraghty and Miller, 1985) and Lower Aquifer Groundwater Quality Assessment (Cavenham, 1989) for addition details. Figures 3 and 4 are potentiometric maps of the Upper and Lower Aquifers, respectively. Table 2 is a summary of recent potentiometric data for the site.

2.1 UPPER AQUIFER

The Upper Aquifer is composed of fine sands and silts with a varying thickness of clay that tends to increase to the south and east and thins to the west. In the vicinity of the Closure Area, at equivalent stratigraphic depths, silts and sands laterally transition to peat and organic clay deposits, which replace the more permeable strata in the western half of the Closure Area. The thickness of the Upper Aquifer ranges from zero to about 20 feet. This aquifer appears to be in direct hydraulic communication with Three Mile Creek.

Throughout the southern half of the site, an underlying Confining Clay is present that separates the Upper Aquifer from the Lower Aquifer. This clay is missing in the northern part of the site and the Upper and Lower Aquifer are not distinct units in this area, i.e., they come together to form one water-bearing unit.

Based on previous pumping tests the horizontal hydraulic conductivity of the Upper Aquifer is 6.3 ft/day. The average linear groundwater velocity was calculated to be 0.14 ft/day, with the flow direction toward Three Mile Creek. Assumptions used to calculate these hydraulic properties include an effective porosity of 0.20 and an average hydraulic gradient of 0.0046 ft/ft.

2.2 LOWER AQUIFER

Underlying the Confining Clay is the Lower Aquifer, a relatively massive, water-bearing sand formation. The composition of the Lower Aquifer varies from silty, fine sands to coarse sands and pea-sized gravel. The thickness ranges from approximately 60 to 110 feet. Borings that have penetrated the entire thickness of the Lower Aquifer have encountered a dense blue-green clay which is referred to at the site as the "Marine" Clay unit.

Using the average horizontal hydraulic conductivity of the Lower Aquifer of 120ft/day, the average hydraulic gradient is 0.0004 ft/ft, and the effective porosity of 0.25, the average linear groundwater flow velocity was calculated to be 0.19 ft/day. This water is generally moving to the southeast toward Three Mile Creek and the Mobile River.

3.0 NATURE & EXTENT OF GROUNDWATER CONTAMINATION

Investigations at the site during the time period from 1985 to the present have indicated the presence of both nonaqueous phase liquids (NAPL) and dissolved contaminants consisting predominantly of polynuclear aromatic hydrocarbons (PAHs) and phenolic compounds typical of wood treating operations that utilize creosote and

pentachlorophenol. These compounds have migrated from the processing and waste containment areas into the surrounding soils and groundwater at the site.

3.1 UPPER AQUIFER

Figure 5 shows the extent of groundwater contamination that is present in the Upper Aquifer outside the HDPE-lined cutoff wall. The map is based on data from the 2023 sampling data for the site, including qualitative data, such as logging notations on soil boring logs. Total groundwater concentrations for the volatile organic constituents, the phenolic constituents, and the PAH constituents from Table 3, are shown for each well in this figure. The majority of the detected constituents are PAHs, with generally lesser quantities of phenolics and volatile constituents.

3.2 LOWER AQUIFER

The present extent of the groundwater contamination in the Lower Aquifer is shown on Figure 6. The map is based on the 2023 sampling data for the site, as summarized in Table 3. Total groundwater concentrations for the volatile organic constituents, the phenolic constituents, and the PAH constituents from Table 3 are shown for each well in this figure. Figure 6 indicates that the contaminants are present downgradient from the Closure Area in the Lower Aquifer.

4.0 EXISTING SITE REMEDIATION SYSTEM

Site specific remedial measures have been developed utilizing the extensive data base for the site. The remediation system for the Mobile facility includes the following elements:

- Combination HDPE-lined soil-bentonite cutoff wall around the closed landfill;
- Internal hydraulic Gradient Control System for the closed landfill;
- Surface Seal (Composite Clay/Synthetic Liner Cap) over the closed landfill;
- Groundwater recovery, treatment and discharge;
- Source reduction and in situ treatment; and,
- Monitoring wells and piezometers.

Each of these remedial measures is discussed in the following sections.

4.1 SYNTHETIC LINED CUTOFF WALL

A high-density polyethylene (HDPE) lined soil-bentonite cutoff wall is installed such that it completely surrounds the area of the former Vacuum Ponds and most of the area of the former Aeration Pond. This cutoff wall provides a physical barrier to prevent the off-site movement of the enclosed non-aqueous phase liquid and soluble groundwater

contaminant plumes that are present in the immediate vicinity of the solidified impoundments within the Upper Aquifer Closure Area. The alignment of the cutoff wall is depicted in Figure 2.

4.2 GRADIENT CONTROL SYSTEM

A hydraulic gradient control system within the area isolated by the cutoff wall effectively controls the Upper Aquifer groundwater elevation within the landfill. This system removes groundwater from the contaminated soils that are contained within the area confined by the cutoff wall. Originally, the gradient control system was pumped primarily from the gradient control system sump (GC SUMP); however, due to cap settlement since installation, new low spots in the gradient control system have developed. To account for the differential settlement of the cap, the gradient control system is now pumped from three (3) locations, GC SUMP and two (2) cleanouts identified to be the new low spots, CO-7 and CO-10. The pumping rate is adjusted such that an inward hydraulic gradient across the cutoff wall is maintained. As shown in Figure 2, the gradient control system consists of a perimeter drainage system and a north-south central lateral.

4.3 SURFACE SEAL

The Closure Area is covered with approximately two (2) feet of compacted clay and also with a synthetic liner that is composed of 0.060-inch HDPE. This dual liner system will virtually stop infiltration within the area surrounded by the cutoff wall. Additionally, this cap continues to the north to seal the area of the former Aeration Pond, which is not included in the cutoff wall enclosed area.

4.4 UPPER AQUIFER GROUNDWATER RECOVERY SYSTEM

In accordance with Cavenham's revised Corrective Action Plan of July 14, 1992, and subsequent modifications of May 5, 2000 and August 14, 2001, a total of twenty-four (24) recovery wells and two (2) recovery trenches have been installed to recover contaminated groundwater from the Upper Aquifer. As shown below, some of these recovery wells serve dual roles as both monitoring wells and recovery wells. These wells are located both within and outside the area encircled by the cutoff wall.

Recovery wells in the Upper Aquifer are as follows:

- Recovery Wells: RW-6, RW-11, RW-12, RW-13, RW-18, RW-19, RW-20, RW-21, RW-23, RW-24, RW-25, RW-28, RW-33, and RW-34;
- Compliance/Recovery Wells: RC-2, RC-3, and RW-1;
- Effectiveness/Recovery Wells: E-1 and the recovery trenches T-1 and T-2;

- Injection/Recovery Wells: A-1, A-2, A-3, A-4, A-5, and A-6;

The locations of these recovery wells and trenches are indicated on Figure 2. Table 1 is a summary of well construction data for both monitoring and remediation wells installed at this site.

4.5 UPPER/LOWER AQUIFER RECOVERY WELLS

Five (5) recovery wells were installed in both the Upper Aquifer and the upper portion of the Lower Aquifer. This portion of the recovery well system is located in the proximity of the three (3) decommissioned storage tanks on the northwestern portion of the site. These wells provide hydraulic containment and contaminant recovery downgradient of the closed landfill.

The recovery wells in the transition zone between the Upper Aquifer and the upper portion of the Lower Aquifer are:

- Recovery Wells: RW-7, RW-29, RW-30, RW-31, and RW-32.

The locations of these recovery wells are indicated on Figure 2.

4.6 LOWER AQUIFER RECOVERY WELLS

The Lower Aquifer recovery well system consists of twelve (12) recovery wells screened in the Lower Aquifer. These wells provide hydraulic containment and contaminant recovery both inside and surrounding the closed landfill.

The recovery wells in the Lower Aquifer are:

- Recovery Wells: RW-8, RW-9, RW-10, RW-35, RW-36, and RW-37;
- Boundary/Recovery Wells: RW-8A and RW-3B;
- Compliance/Recovery Well: RW-2;
- Effectiveness/Recovery Wells: RW-3A, RW-4, and RW-5;

All of the wells are currently installed at the locations indicated on Figure 2. Iron fouling is occurring in the downgradient wells RW-8, RW-8A, RW-9, and RW-10. These wells are being cycled on and off periodically with the exception of RW-9, which has been shut down. Wells RW-35, RW-36, and RW-37 were installed to assist in recovery in order to allow RW-8, RW-8A, RW-9, and RW-10 to be pumped on an as needed basis.

4.7 UPPER AQUIFER INJECTION WELLS

The CAP calls for one (1) injection well, I-1, in the Upper Aquifer in the vicinity of well RC-1. Additionally, wells A-1 through A-6 within the landfill are available to be utilized for

injection once the level of recoverable oil diminishes. The locations of these wells are indicated on Figure 2. Wells A-1 through A-6 were designed to be used as either recovery or injection wells to assist with contaminant recovery. As these wells were designed to perform dual roles, they are also listed above in the recovery well section. Presently, these wells are not actively being utilized as recovery wells or injection wells.

Injection well I-1 was installed on November 1, 1994. This well was placed on-line in February, 1995.

4.8 LOWER AQUIFER INJECTION WELLS

The CAP calls for installation of two (2) injection wells, I-2 and I-3, into the Lower Aquifer along the western side of the closure area. These two (2) wells and the existing well B-48A will be utilized as injection wells. The locations of these wells are indicated on Figure 2.

Injection wells I-2 and I-3 were installed during November 2-8, 1994. Cavenham placed these wells on-line during March and April, 1995. Injection well I-2 was replaced with injection well I-2A in August, 1995.

4.9 AIR SPARGING WELLS

The May 5, 2000 modification of the CAP proposed air sparging well locations within the confines of the Closure Area. These wells were subsequently installed and operated until approximately 2006 when entrapment of the air was noted under the synthetic liner covering the Closure Area. No damage to the liner was observed or believed to be present. The air sparge system was shut down and remains inoperable. To ensure unpermitted discharges do not occur the compressor that supplied the air was isolated from the system and all piping and wells were sealed. The ten (10) air sparging well locations are indicated on Figure 2. The wells are numbered AS-1 through AS-10.

4.10 RECOVERED GROUNDWATER TREATMENT SYSTEM

A water treatment system has been installed to treat the groundwater recovered during the site remediation. The treatment system is based on a treatment train approach and consists of gravity settling, fixed film microbial degradation, and activated carbon polishing. Figure 7 is an “as-built” drawing of the treatment system.

4.11 MONITORING WELLS & PIEZOMETERS

Monitoring of the groundwater quality and elevation during the corrective action period is necessary to assess the progress of the remediation and to assure hydraulic control of the contaminant plume. To monitor the progress of the remediation, groundwater quality

is monitored in the Upper and Lower Aquifers. Site piezometers are utilized to evaluate the hydraulic behavior of the aquifer as it responds to the corrective action pumping and injection activities.

5.0 PROPOSED REMEDIAL MEASURES

Pursuant to the site's Resource Conservation and Recovery Act (RCRA) Permit Condition I.C.12, CFI would like to propose to the Department the conversion of the two air sparging wells into recovery wells, the decommissioning of the remaining air sparging wells and to plug and abandon twelve (12) recovery wells. Each one of these is addressed in the following sections. All well construction, installation, and abandonment procedures will follow the Alabama Environmental Investigation and Remediation Guidance Document (AEIRG) revision 4.0, dated February 2017.Table 1 summarizes the construction of each well currently on site and which wells will be decommissioned or converted into different roles.

5.1 INSTALLATION OF RECOVERY WELLS

Two air sparging wells, AS-03 and AS-04, will be over-drilled and new recovery wells will be installed in the same location. The recovery wells are planned to be constructed using 4-inch 316 stainless steel with 10 feet of continuous wrapped screen. The total depth is anticipated to be approximately 29 feet below ground surface. The new recovery wells will match the original depths of the air sparging wells, and will not puncture the Confining Clay layer. Figure 2 includes the location of the site's wells. The drilling will be performed by either direct push type drilling rig, a sonic rig or equivalent technology. Following installation, updated survey data will be collected, boring logs will be completed, and all appropriate documents will be updated via a minor permit modification. Well construction details are found in Figure 8. The proposed recovery wells will be constructed in general accordance with the AEIRG.

The installation of the proposed recovery wells will be through the HDPE liner installed over the impoundment. To ensure the integrity of the cap is maintained a HDPE boots with a bentonite sealant, or equivalent as manufacturer's recommendation, will be installed.

Once installed, the recovery wells will be equipped with stainless steel air lift pumps. The anticipated rate of withdrawal is expected to be approximately 0.5 to 2 gallons per minute (gpm). If the recovery wells are able to produce a greater amount of water down-hole

electrical pumps or larger air pumps may be installed. The wells will be plumbed and all produced water will be routed through the on-site treatment system.

5.2 DECOMMISSIONING WELLS

From 2001 through 2002, CFI installed fifteen (15) recovery wells and ten (10) air sparging wells to optimize product recovery and remediation around the site. This install, while appropriate at the time, is now deemed unproductive to the site's remedial design, with the exception of RW-35, RW-36, and RW-37. The following paragraphs provide the reasoning behind the decision to remove these wells from the site's regulatory record.

The site's air sparging wells are proposed to be plugged and abandoned and the remedial technology removed from the site's permit, with the exception of AS-03 and AS-04, which will be converted into recovery wells. The air sparging system was abandoned over 15 years ago when air was being trapped under the liner and producing "bubbles" that threatened the integrity of the liner. The compressor that supplies air for the system was disconnected indefinitely in January 2022. The air sparging wells AS-01, AS-02, AS-05, AS-06, AS-07, AS-09, and AS-10 are proposed to be plugged and abandoned.

Twelve (12) of the site's recovery wells are proposed to be plugged and abandoned due to ineffectiveness and cumbersome operations and maintenance. The wells were constructed as 2-inch recovery wells and were equipped with air lift pumps. The combination of the smaller diameter recovery well, pump type, and location proved to be inefficient and produced extra work for the site's personnel to keep the wells producing water for treatment. The wells were continually being clogged and the small pumps proved inefficient at producing the amount of water that was considered adequate. The recovery wells RW-20, RW-21, RW-23, RW-24, RW-25, RW-28, RW-29, RW-30, RW-31, RW-32, RW-33, and RW-34 are proposed to be plugged and abandoned.

The proposed plugging and abandonment of the wells will be conducted in general accordance with the AEIRG. All work will be overseen by a qualified environmental geologist/engineer and will be performed by a licensed driller.

5.3 RECOVERY WELL RENOVATION

At the end of 2023, CFI measured total depths of the site's wells and are included in Table 4. Several wells were determined to have several feet of sediment at the bottom. These wells were redeveloped to remove the sediment. One well, RW-10, continued to indicate significant amounts of sediment based on the difference of the measured total depth and the original total depth of the well at the time of installation. CFI proposes to perform further redevelopment of this well to attempt to remove the remaining sediment by using

surging techniques and aggressive pumping. All water generated will be contained and have flocculent added to help the sediment settle out before the water is treated in the site's water treatment unit. The sediment will then be containerized, characterized, and disposed of at a properly permitted facility. If the recovery well cannot be rehabilitated, it will be replaced by over drilling and a new identical recovery well installed. All work will follow the AEIRG. All work will be overseen by a qualified environmental geologist/engineer and will be performed by a licensed driller.

5.4 CORRECTIVE ACTION PERIOD

CFI plans to continue the corrective action activities as described above until site conditions change to prevent potential risk to human health and the environment. At a minimum, CAP re-evaluation will be performed during subsequent permit renewal applications. In determining the long-term operational costs of corrective action, CFI proposes to continue corrective action activities as described above for the next 10 years and a reduced monitoring schedule for the following 20 years.

6.0 CONCLUSION

The modifications to remedial system will continue to meet the remedial objectives for the site. The modifications to the remedial system will allow for more operational efficiency while removing legacy remedial components that are no longer used or necessary.

* - Denotes wells proposed to be decommisioned.
** - Denotes wells proposed to be converted into recovery wells. This table will be updated via minor permit modification once installed.
ft-msl - Elevation in feet relative to mean sea level
ft-bls - Feet below land surface

Aquifer:
UA - Upper Aquifer
UL - Upper portion of Lower Aquifer
IL - Intermediate portion of Lower Aquifer
LL - Lower portion of Lower Aquifer

Casing Material:
SS - Stainless Steel
PVC - Polyvinylchloride
HDPE - High Density Polyethylene

Use:
A - Air Sparger
B - Boundary
C - Compliance
E - Effectiveness
I - Injection
P - Piezometer
R - Recovery
X - Background

Notes:
RW-18 - formerly AS/RW-10
RW-19 - formerly AS/RW-8
RW-20 - formerly AS/RW-9
AS-8 - formerly RW/AS-20
AS-9 - formerly RW/AS - 22
AS-10 - formerly RW/AS-26

ATTACHMENT S
SWMU AND AOC DESCRIPTIONS

Solid Waste Management Units
Cavenham Forest Industries LLC
Mobile, Alabama

1.0 Introduction

This section presents descriptions of SWMUs identified during the PR and VSI of the Cavenham Forest Industries LLC facility located in Mobile, Alabama. A detailed description of each unit is included as Exhibit S-1. Much of the information contained in this exhibit is excerpted from the *RCRA Facility Assessment* (RFA) performed by A.T. Kearney, Inc. in November of 1991. Table S-1 summarizes pertinent information regarding the SWMUs. A SWMU location map is provided in Figure S-1.

2.0 SWMU Descriptions

The following are requirements for Solid Waste Management Unit (SWMU) description under ADEM Administrative Code Rule 335-14-8-.05(5) for facilities seeking a permit. Also included is the location of information necessary to satisfy each requirement.

335-14-8-.02(5)(d)Information requirements for solid waste management units.
(d) Information requirements for solid waste management units.

1. The following information is required for each solid waste management unit at a facility seeking a permit:

(i) The location of the unit on the topographic map required under 335-14-8-.02(5)(b)19.

See Figure S-1 for a site map depicting SWMU locations.

(ii) Designation of type of unit.

See Table S-1 for a summary of each SWMU with type of unit designated. For additional detail see Exhibit S-1.

(iii) General dimensions and structural description (supply any available drawings).

Structural descriptions are provided for each SWMU in Exhibit S-1 where applicable.

(iv) When the unit was operated.

Periods of operation are provided in summary Table S-1. Additional detail is provided in Exhibit S-1.

(v) Specification of all wastes that have been managed at the unit, to the extent available.

This is information is summarized in Table S-1. Additional detail is provided in Exhibit S-1.

2. The owner or operator of any facility containing one or more solid waste management units must submit all available information pertaining to any release of hazardous wastes or hazardous constituents from such unit or units.

Table S-1 provides a summary of descriptive information for each unit. The RCRA Facility Assesment conducted by A.T. Kearney in 1991, provides additional descriptive information and information regarding releases. Reference Foster Wheeler Environmental Corporation *Confirmatory Sampling and RCRA Facility Investigations, Volumes 1 through 3, January 1996,* for a detailed account of releases of hazardous wastes and hazardous constituents from units.

3. The owner/operator must conduct and provide the results of sampling and analysis of groundwater, land surface, and subsurface strata, surface water, or air which may include the installation of wells, where the Department ascertains it is necessary to complete a RCRA Facility Assessment that will determine if a more complete investigation is necessary.

CFI has conducted a RCRA Facility Investigation and confirmatory sampling of the solid waste management units and areas of concern identified in the RCRA Facility Assessment. The results of the investigation are provided in the Foster Wheeler Environmental Corporation report *Confirmatory Sampling and RCRA Facility Investigations, Volumes 1 through 3* (January 1996). Provided below is a summary of actions recommended at solid waste management units and responses by CFI:

SWMU 3

Contamination was detected in the shallow soils and groundwater at the storage tanks located on the northern portion of the property. Recommendations included removal of shallow soils and treatment in the on-site corrective action management unit (CAMU) and continued operation of the nearby recovery well RW-7.

CFI revised the facility corrective action plan in May 2000, by proposing four additional recovery wells for the tank farm area along with other modifications. CFI obtained ADEM approval for the plan, *Corrective Action Plan Amendment* (May 2000) in correspondence dated November 21, 2000.

SWMU 19

Significant levels of wood treating constituents were observed in portions of the woodwaste fill material at the former treated lumber storage pile (south of current hazardous waste management

area). Recommendations included the installation of test pits or trenches to obtain additional data as part of a corrective measures study.

CFI conducted a corrective measures study for SWMU 19 during 1997. The results of the study were presented in the *Corrective Measure Study SWMU 19* report (August 1997). The report recommended excavation of the material in this area and treatment in the on-site corrective action management unit. This material was excavated and treated in the CAMU during 2000.

SWMU 27

Residual soil contamination was observed in soils stockpiled at SWMU 27 (behind the tank farm). Recommendations included removal and treatment of the stockpiled soils and the top 2 feet of the surficial soils beneath the pile. The material was to be placed in the on-site corrective action management unit for treatment.

CFI excavated this material during 1997 and treated it with the other soils within CAMU.

Culvert SWMU

During soil corrective action activities at the site CFI discovered a subsurface culvert that appeared to have routed liquids away from the former process area. This discovery was reported to ADEM in correspondence dated November 1, 1999. Test pits confirmed that a culvert approximately 18 inches in diameter and composed of concrete in some areas and iron or steel in others traversed the site between Three Mile Creek and the present water treatment system. The trend of the piping suggested it continued beneath the present water treatment system and likely terminated within the former process area.

CFI fully excavated the culvert and the surrounding contaminated soil in the area between Three Mile Creek and the existing treatment system. The contaminated soils were placed in the on-site corrective action management unit and treated with other soils. CFI investigated the soils on the north side of the water treatment system in December, 2002. Soil samples from two borings in this area did not detect constituents of concern [*CAMU Certification Report* (May 2004)].

CAMU Certification Report

CFI's *CAMU Certification Report* (May 2004) summarizes the construction, operation and closure of two Corrective Action Management Units (CAMUs) for the treatment of soil. During the remediation approximately 32,365 cubic yards of on-site soils were excavated and treated in the CAMUs to meet established health-based cleanup criteria. The report is included as Attachment H of the Post Closure Permit Application.

4. The owner or operator must provide documentation of compliance with the requirements of the Uniform Environmental Covenants Program in ADEM Admin. Code div. 335-5 for all solid waste management units and areas of concern (including regulated

units) for which remediation does not achieve the standard of unrestricted use.

In April 1995, CFI proposed a modification of the post closure permit to conduct on-site soil remediation. The modification designated two CAMUs and provided risk-based action levels for cleanup of soil by bioremediation. Following ADEM approval the two CAMUs were constructed and during the period November 1997 until January 2002, approximately 32,365 cubic yards of on-site contaminated soils were excavated and treated within the CAMUs. Following treatment, the soils were returned to the site and the CAMUs were closed in accordance with the plan. Attachment H of the Post Closure Permit provides additional information on the construction and operation of CAMUs in the *CAMU Certification Report* (May 2004).

EXHIBIT S-1

DETAILED DESCRIPTION OF SWMUs
Excerpt from *RCRA Facility Assessment* (RFA)
by A.T. Kearney, November 1991

III. SWMU AND AOC DESCRIPTIONS

This section presents descriptions of Solid Waste Management Units (SWMUs) and Areas of Concern (AOCs) identified during the PR and VSI of the Cavenham Forest Industries facility. The current units at the facility are described first, followed by the former units which have all been removed from the site. The former units are presented in the order in which they handled the primary waste (K001), followed by storage and miscellaneous units.

A SWMU and AOC location map is provided in Figure III-1 located in Appendix D. Figure III-2, also in Appendix D, is an aerial photograph of the site taken in the mid- to late-1970's, which illustrates the locations of the regulated units at the facility. The following designations are used to designate release pathways:

L (Low)	minimal potential for release
M (Medium)	moderate potential for release
H (High)	evidence suggests that release(s) have occurred
U (Unknown)	no information is available.

The photograph numbers correspond to the numbering system of the Photographic Log provided in Appendix B.

SWMU NUMBER: 1 **PHOTOGRAPH NUMBER:** 1.1, 1.2, 1.3, 1.4, 1.5 2.1, 3.1, 7.1

NAME: Capped Landfill Unit

TYPE OF UNIT: Landfill

PERIOD OF OPERATION: 1988 to Present

PHYSICAL DESCRIPTION AND CONDITION: This unit encompasses an area of approximately 160,000 square feet in the west central portion of the facility. It consists of a clay-capped landfill which is completely encapsulated by a low permeability, lime-slurry, cutoff wall. A leachate collection system (gradient control system) is present at the base of the unit. The cover of the unit consists of a gas collection/venting system, a low permeability clay liner which is overlain by a synthetic liner, a topsoil drainage control system, topsoil and vegetation. SWMUs encased in the landfill with their associated wastes include the Vacuum Ponds (SWMU 12), the Aeration Pond (SWMU 16), the Container Storage Area (SWMU 21), the Sand Filtration Beds (SWMU 14), portions of the Former NPDES Drainage Ditch (SWMU 17), the North Tar Deposit (SWMU 22), the Creek Tar Deposit (SWMU 23), the Spot Deposits (SWMU 24), the Treated Lumber Waste Pile (SWMU 19), portions of the Treated Wood Storage Areas (AOC A), and various poles, demolition debris, and tank sections derived from the site demolition activities. The landfill covers the former locations of the Creosote Recovery System (SWMU 8), the Penta Recovery System (SWMU 9), the Vacuum Ponds (SWMU 12), the Flocculation Tank (SWMU 13), the Sand Filtration Beds (SWMU 14), the Aeration Tank (SWMU 15), the Container Storage Area (SWMU 21), the Former UST Location (AOC E), and portions of the Aeration Pond (SWMU 16), the Former NPDES Drainage Ditch (SWMU 17), and the Creosote Wastewater Disposal Area (SWMU 18). Details of the waste contained in the SWMUs are included in the individual SWMU descriptions.

The Capped Landfill Unit is complimented by a ground-water recovery well network consisting of seven recovery wells screened over two aquifers. The recovery system was not in operation at the time of the VSI, but was to become operational by March 1992. During the VSI, facility representatives discussed the possibility of pursuing efforts to remediate the wastes contained within the landfill as well.

Closure certification of the unit was accepted by ADEM on April 8, 1991. At the time of the VSI, the landfill was covered with thick vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit contains wood treating wastes including K001 sludge and constituents of creosote, pentachlorophenol, and petroleum derivatives.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was observed during the VSI or identified in the available file material.

RECOMMENDATIONS:
No Further Action (*)
Confirmatory Sampling ( )
RFI Necessary ( )

REFERENCE(S): 1, 2, 4, 9, 12, 28, 38, 87, 113, 118, 119

COMMENTS: * Continued efforts towards remediation of the Capped Landfill Unit (SWMU 1) and continued corrective action for contaminated ground water is suggested. Caution should be taken during ground water removal to ensure that the stability/integrity of the landfill is not weakened.

SWMU NUMBER: 2A-F **PHOTOGRAPH NUMBER:** 1.2, 2.1, 2.2, 2.3

NAME: Pilot Study Ground-Water Treatment System

TYPE OF UNIT:

SWMU 2A	Blue Holding Tank
SWMU 2B	Oil/Water Coalescing Separator
SWMU 2C	Receiving Drum
SWMU 2D	TM-100 Separator
SWMU 2E	TM-100 Carbon Adsorption Unit
SWMU 2F	Red Holding Tank

PERIOD OF OPERATION: Approximately August 1991 to Present

PHYSICAL DESCRIPTION AND CONDITION: This unit is located inside the security fence directly south of the Capped Landfill Unit (SWMU 1). Ground water contaminated with K001 wastes is collected from the leachate collection system (gradient control system) and the ground-water recovery wells. The contaminated ground water is pumped via HDPE piping of approximately 2-inch diameter, into the 250,000-gallon Storage Tank No. 2 (SWMU 3B) in the northwest area of the site. From the storage tank the water is pumped to the Blue Holding Tank (SWMU 2A) which is located at the treatment system. The wastewater is then passed successively through each unit within the system (Oil/Water Coalescing Separator, Receiving Drum, TM-100 Separator, TM-100 Carbon Absorption Unit, and Red Holding Tank) until the treatment process is complete, at which time the water is returned to the 160,000-gallon Storage Tank No. 1 (SWMU 3A). All six units sit on a concrete pad with an 8-inch concrete curbing. The system processes wastewater at a rate of 5 gallons per minute (gpm).

Blue Holding Tank (SWMU 2A): This unit consists of an estimated 20,000-gallon steel tank located on the east end of the ground-water treatment system concrete pad. At the time of the VSI, the top of the tank was open and it was almost full of water. Phenol odors were emanating from the unit and an oily sheen was visible on the surface of the water in the tank. Although no leaks were observed from the tank, the concrete pad underlying the tank was stained in places.

Oil/Water Coalescing Separator (SWMU 2B): This unit consists of an estimated 500-gallon red steel tank located adjacent to the west side of the Blue Holding Tank (SWMU 2A). The unit, which is the first treatment unit in the system, separates the light and heavy immiscible oils from the wastewater. The treated

wastewaters flow into a black 55-gallon Receiving Drum (SWMU 2C). Upon completion of the pilot test, the oil recovered from the unit will be incinerated at Allied Chemical in Birmingham, Alabama. No releases were observed from this unit.

Receiving Drum (SWMU 2C): This unit consists of a black 55-gallon drum located directly south of the Oil/Water Coalescing Unit (SWMU 2B). The drum is used to temporarily store wastewater from the separator prior to treatment in the TM-100 Separator (SWMU 2D). No releases were observed from this unit.

TM-100 Separator (SWMU 2D): This unit consists of a gray 100-gallon steel tank located west of the Oil/Water Coalescing Separator (SWMU 2B). The unit is manufactured by Technical Minerals, Inc. (a division of Ergon) and contains an internal element of bentonite clay bonded with an amine, which adsorbs dissolved and suspended oils from the wastewater. The treated wastewater flows into the TM-100 Carbon Adsorption Unit (SWMU 2E). Upon completion of the pilot study, the contaminated residue will be incinerated at Allied Chemical in Birmingham, Alabama. No releases were observed from this unit.

TM-100 Carbon Adsorption Unit (SWMU 2E): This unit consists of a 100-gallon carbon steel tank located north of the TM-100 Separator Unit (SWMU 2D). Like the TM-100 Separator, the unit is manufactured by Technical Minerals, Inc. (a division of Ergon). This unit is the last treatment stage in the Pilot Study Ground-Water Treatment System. The treated wastewater flows from this unit into the Red Holding Tank (SWMU 2F). The contaminated carbon from this unit will reportedly be incinerated at Allied Chemical in Birmingham, Alabama. No releases were observed from this unit.

Red Holding Tank (SWMU 2F): This unit consists of an estimated 500-gallon, open-topped, steel tank. The unit temporarily holds the treated ground water prior to being pumped via HDPE tubing back to Storage Tank No. 1 (SWMU 3A). No releases were observed from this unit.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit manages ground water contaminated with creosote and pentachlorophenol (K001) constituents.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): Some wetness was visible on the concrete pad underlying the Blue Holding Tank (SWMU 2A), but no releases to soil outside the pad were observed at the time of the VSI.

RECOMMENDATIONS:

No Further Action	(*)
Confirmatory Sampling	( )
RFI Necessary	( )

REFERENCE(S): 1

COMMENTS: * This SWMU is a temporary system (pilot study) designed to test the efficiency of the TM-100 units in remediating the contaminated ground water. It will ultimately be replaced with a permanent system. The associated wastes generated by the system should be disposed at a permitted facility. In addition, the permanent treatment system should have sufficient secondary containment to contain the full capacity of the largest tank within the unit to prevent the possible release of contaminated ground water to the surrounding soil.

SWMU NUMBER: 3A-C **PHOTOGRAPH NUMBER:** 1.3, 3.1, 3.2 3.3, 3.4, A.1

NAME: Storage Tanks (3)

TYPE OF UNIT: Above-Ground Tanks;
SWMU 3A Tank No. 1
SWMU 3B Tank No. 2
SWMU 3C Tank No. 3

PERIOD OF OPERATION: 1938 to Present

PHYSICAL DESCRIPTION AND CONDITION: This unit is located in the northwestern corner of the facility directly south of the facility office. The unit consists of three above-ground storage tanks formerly used to store creosote and pentachlorophenol carrier (No. 2 diesel fuel with a co-solvent for mixing) from 1938 until 1985; the tanks have been used as part of the NPDES water treatment system since 1985. The tanks are constructed of steel and do not have any associated concrete containment.

The southernmost tank (Tank No. 1, SWMU 3A) has a capacity of 160,000 gallons and was used to store pentachlorophenol carrier. The tank was cleaned as part of the closure activities and currently contains 11,000 gallons of treated ground water and rainfall runoff which was collected during the closure activities. Facility representatives could not provide details on the cleaning of the tanks. The water in the tank will be discharged under NPDES Permit AL0001104.

The center tank (Tank No. 2, SWMU 3B) has a capacity of 250,000 gallons and was used to store creosote product. Since 1985 the tank has been used to store construction wastewater from corrective action activities and contaminated ground water from the recovery wells. The tank currently contains approximately 5,000 gallons of untreated water. Water in the tank is pumped to the Pilot Study Ground-Water Treatment System (SWMU 2) through HDPE lines.

The northernmost tank (Tank No. 3, SWMU 3C) has a capacity of 750,000 gallons and was used to store creosote product. The tank was empty at the time of the VSI. The three tanks are surrounded by a four-foot high earthen dike which reportedly has the capacity to contain a 900,000 gallon release; no other concrete or impermeable containment features are present. No integrity

tests have been performed on the tanks. According to the facility representatives, no spills or leaks have been recorded or suspected in the tank farm area.

At the time of the VSI, the area was overgrown with vegetation. Some standing water (probably rain water according to facility representatives) was observed within the containment area. Former discharge valves on the tanks (recently sealed shut) were almost at ground level. The tanks appeared to either be settling, or sediments in the containment area have built up around the base of the tanks.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The units formerly managed creosote and pentachlorophenol products, along with petroleum-based (No. 2 fuel oil) carrier solutions. Since 1985 the units have managed treated and untreated, contaminated ground water.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (U)
Ground Water (U) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was observed during the VSI or identified in the available file material.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	(*)
RFI Necessary	( )

REFERENCE(S): 1, 105

COMMENTS: * Due to the age of the tanks and the lack of secondary containment, integrity testing of the units is suggested to insure that contaminated ground water will not be released to surrounding soil. If the integrity of any of the tanks is impaired, then confirmatory sampling may be warranted. In addition, the stability of the tanks relative to ground surface should be investigated to ensure that the tanks are not settling or shifting.

SWMU NUMBER: 4 **PHOTOGRAPH NUMBER:** 4.1, 4.2, 4.3

NAME: Current NPDES Drainage Ditch

TYPE OF UNIT: Drainage Ditch

PERIOD OF OPERATION: 1989 to Present

PHYSICAL DESCRIPTION AND CONDITION: This unit is located in a north to south orientation along the western boundary of the facility. To the south, the ditch intersects the Former NPDES Drainage Ditch (SWMU 17) prior to discharging to Threemile Creek (AOC D). The ditch was designed to channel site surface runoff to the creek after the original NPDES drainage ditch was excavated during field closure activities. This unit will handle all future discharge under the NPDES permit for the facility. The unit is located within the Former Creosote Wastewater Disposal Area (SWMU 18) where K001 wastewaters were disposed until approximately 1973.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit may have received process wastewaters in the past containing creosote and pentachlorophenol constituents.

RELEASE PATHWAYS: Air (L) Surface Water (U) Soil (U)
Ground Water (U) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was identified in the available file material. An oily sheen was present on the water surface at the time of the VSI. It has not been established whether the sheen was naturally occurring organic derivatives from the underlying peats or potential leachate from the Creosote Wastewater Disposal Area (SWMU 18). This unit is located within the Creosote Wastewater Disposal Area (SWMU 18).

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	( )
RFI Necessary	(*)

REFERENCE(S): 1

COMMENTS: * Sampling of the ditch surface water and sediment is suggested to determine if the oily substance on the ditch surface contains hazardous constituents. The investigation should be incorporated within the investigation of the Creosote Wastewater Disposal Area (SWMU 18).

SWMU NUMBER: 5 **PHOTOGRAPH NUMBER:** 1.5, 5.1, 6.1

NAME: Cylinder Door Sumps

TYPE OF UNIT: Concrete Sumps

PERIOD OF OPERATION: Approximately 1976 to November 1981

PHYSICAL DESCRIPTION AND CONDITION: The unit consisted of four concrete sumps, one located beneath each door of the two treatment cylinders used at the facility. The treatment cylinders and sumps were located in the central portion of the site, east of the Capped Landfill Unit (SWMU 1, a current SWMU). The rectangular sumps were constructed of concrete, each measuring approximately 10 feet by 15 feet by four feet deep.

The unit received residual treatment solutions from the cylinders when the treated lumber was removed. The drainage consisted of either used creosote oils or used pentachlorophenol solution, depending upon the treatment utilized. The collected solution was then transferred to the Creosote Recovery System (SWMU 8) or the Penta Recovery System (SWMU 9) as appropriate.

The facility representative had no recollection of integrity testing being performed on the unit or of it leaking. The unit was reportedly removed during the closure activities at the site and visual contamination was placed within the Capped Landfill Unit (SWMU 1). However, no soil sampling was performed to confirm that all contaminated soil was removed. At the time of the VSI, the former location of the unit was sparsely covered with vegetation. The former units were located outside the containment wall of the Capped Landfill Unit (SWMU 1), but possibly within the security fence surrounding the landfill.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit received drainage containing creosote oils and pentachlorophenol.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (U)
Ground Water (U) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): An Alabama Water Improvement Commission (AWIC) Inspection Report from February 4, 1976 suggested that concrete curbing be added around the separation units and at the ends of the treatment cylinders. The recommendation was based on the observation of the ground surface covered with black oily liquids with no provision for containment. In addition, ground-water contamination has been confirmed in the upper aquifer below this area of the facility in well RC-1. Evidence of contamination was observed during the drilling of boring B-45 in the vicinity of this unit.

RECOMMENDATIONS:

No Further Action ( )
Confirmatory Sampling ( )
RFI Necessary (*)

REFERENCE(S): 1, 2, 105, 133

COMMENTS: * The investigation of the former location of these sumps should be performed in conjunction with the other units located in the treatment area.

SWMU NUMBER: 6 **PHOTOGRAPH NUMBER:** 1.5, 5.1, 6.1

NAME: Cylinders Sump

TYPE OF UNIT: Concrete Sump

PERIOD OF OPERATION: Approximately 1976 to November 1981

PHYSICAL DESCRIPTION AND CONDITION: The cylinders sump was located beneath the midsections of both treatment cylinders, in the central portion of the facility. The unit was described as concrete, measuring 50 feet long, 14 feet wide, and three feet deep. Concrete curbing was added around the eastern side of the treatment cylinders in approximately 1981. The unit received drippage from the treatment cylinders and the connecting piping. The drippage may have contained creosote oils or pentachlorophenol depending upon the treatment in use. Liquids collected in the unit were pumped to the Creosote and Penta Recovery Systems (SWMUs 8 and 9), depending upon the solution used for treatment.

Although the treatment cylinders were periodically tested for integrity, the containment structures have no record of integrity testing. The unit was removed during the closure activities at the site and visual contamination was placed within the Capped Landfill Unit (SWMU 1). However, no soil sampling was performed to confirm that all contaminated soil was removed. At the time of the VSI, the former location of the unit was sparsely covered with vegetation. The former unit was located outside the containment wall of the Capped Landfill Unit (SWMU 1), but possibly within the security fence surrounding the landfill.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit received drainage containing creosote oils and pentachlorophenol.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (U)
Ground Water (U) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): An AWIC Inspection Report from February 4, 1976 suggested that concrete curbing be added around the separation units and at the ends of the treatment cylinders. The recommendation was based on the observation of ground surface covered with black oily liquids with no provision

for containment. Ground-water contamination has been confirmed in the upper aquifer below this area of the facility. In addition, evidence of contamination was observed during the drilling of boring B-45 in this area.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	( )
RFI Necessary	(*)

REFERENCE(S): 1, 2, 105, 133

COMMENTS: * The RFI of the former location of this sump should be performed in conjunction with the other units located in the treatment area. Since the units have been removed and the area backfilled, the soil samples should be taken at sufficient depth to reach native soil which has not been manipulated.

SWMU NUMBER: 7 **PHOTOGRAPH NUMBER:** 1.5, 6.1, 7.1

NAME: Cylinder Drip Tracks

TYPE OF UNIT: Drip Tracks

PERIOD OF OPERATION: 1938 to November 1981

PHYSICAL DESCRIPTION AND CONDITION: The unit extended north from the treatment cylinders in the central area of the facility. The unit consisted of railroad tracks on which charges of treated lumber were held immediately after treatment. According to the facility representative, the unit did not have a concrete base or containment measures. Reportedly the lumber treated with pentachlorophenol was essentially dry when removed from the cylinders. However, the representative was not familiar with the creosote process and aerial photographs of the site dating from the mid- to late-1970's show that the area was darkly stained. Any visibly contaminated areas were reportedly excavated during closure activities and deposited in the Capped Landfill Unit (SWMU 1). However, no soil sampling was performed to confirm that all contaminated soil was removed. At the time of the VSI, the former location of this unit was covered with grass.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit received drippage of creosote oils and possibly pentachlorophenol solution.

RELEASE PATHWAYS:

Air	(L)	Surface Water	(L)
Soil	(H)		
Ground Water	(H)	Subsurface Gas	(L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): An aerial photograph of the site taken during the mid- to late-1970's shows the drip tracks were darkly stained.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	(*)
RFI Necessary	( )

REFERENCE(S): 1, 2, 129, 133

COMMENTS: * Since the units have been removed and the area backfilled, the soil samples should be taken at sufficient depth to reach native soil which has not been manipulated.

SWMU NUMBER: 8A-C

PHOTOGRAPH NUMBER: The unit is located within SWUM 1

NAME: Creosote Recovery System

TYPE OF UNIT: Oil Recovery Sumps

PERIOD OF OPERATION: Approximately 1938 to 1985

PHYSICAL DESCRIPTION AND CONDITION: The unit was located west of the treatment area, directly south of the boiler house, in the central area of the facility. It consisted of one concrete baffled sump (SWMU 8A) and two successive oil/water separation sumps (SWMUs 8B and 8C).

During the steam-conditioning cycle in the treatment cylinders, the condensate would wash the oil remaining on the walls and in the bottom of the cylinder from the previous treatment cycle out to the exhaust pipe (prior to approximately 1976) or to the Cylinder Door Sumps (SWMU 5). According to the Spill Prevention Control and Counter-measures (SPCC) plan for the facility, a Collection Tank (SWMU 10A) was utilized to hold the condensate drainage from the treatment cylinders prior to routing the wastewater through this unit. The used solution containing creosote oils was collected in an oil collection sump (SWMU 8A, also referred to as a tank by facility representatives), where the mixture was heated to force any water to the surface. The denser reclaimed creosote oil was then pumped from the bottom of the sump to the creosote working tanks and the water on top was sent through the two oil/water API separators (SWMUs 8B and 8C). The separation sumps are referred to by facility representatives as tanks with a capacity of approximately 2000 gallons each. Wastewater exiting the oil/water separation units was released to another Collection Tank (SWMU 10B) according to an AWIC facility inspection in 1976. From here, the water was released to the Vacuum Ponds (SWMU 12). Prior to 1966, all effluent from the unit was discharged through a pipeline to Threemile Creek (AOC D). Current facility representatives were unaware of the pipelines existence or use.

The unit was reportedly removed during the closure activities at the site and placed along with any visual contamination into the Capped Landfill Unit (SWMU 1). The former unit was located within the cutoff wall of the present Capped Landfill Unit (SWMU 1). At the time of the VSI, the area was covered with vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed condensate wastewater containing creosote oils.

RELEASE PATHWAYS:

Air	(L)	Surface Water	(L)	Soil	(L)
Ground Water	(L)	Subsurface Gas	(L)		

HISTORY AND/OR EVIDENCE OF RELEASE(S): An AWIC Inspection Report from February 4, 1976 suggested that concrete curbing be added around the separation units and at the ends of the treatment cylinders. The recommendation was based on the observation of ground surface covered with black oily liquids with no provision for containment. An April 17, 1985 ADEM inspection noted open vats of oil or creosote at the oil recovery system south of the boiler house as a potential source of contamination for ground water. In addition, ground-water contamination has been confirmed in the upper aquifer below this area of the facility.

RECOMMENDATIONS:

No Further Action	(*)
Confirmatory Sampling	( )
RFI Necessary	( )

REFERENCE(S): 1, 2, 59, 105, 133, 142, 143, 144

COMMENTS: * Continued efforts towards remediation of the Capped Landfill Unit (SWMU 1) and continued corrective action for contaminated ground water is suggested.

SWMU NUMBER: 9A-E **PHOTOGRAPH NUMBER:** The unit is located within SWUM 1

NAME: Penta Recovery System

TYPE OF UNIT: Oil Recovery Sumps

PERIOD OF OPERATION: Unknown to November 1981

PHYSICAL DESCRIPTION AND CONDITION: The unit was located west of the treatment area, directly south of the boiler house, in the central area of the facility. It consisted of five oil/water separation sumps (SWMUs 9A-E). The sumps were referred to by facility representatives as tanks with a capacity of approximately 2000 gallons each. It was unclear from the file material and from speaking with the facility representatives as to whether the separators were the same as or separate from the separators used in the Creosote Recovery System (SWMU 8). According to the SPCC plan for the facility, a Collection Tank (SWMU 10A) was utilized to hold the condensate drainage from the treatment cylinders prior to routing through this unit. Condensate drainage from the treatment cylinders containing pentachlorophenol was routed through the unit to recover the pentachlorophenol solution. The pentachlorophenol solution contained No. 2 fuel oil (diesel) which caused the solution to float. The solution was drawn from the surface of the water in the sumps, and the remaining wastewater was then discharged to the Vacuum Ponds (SWMU 12). Prior to 1966, all effluent from the unit was discharged through a pipeline to Threemile Creek (AOC D). Current facility representatives were unaware of the pipelines existence or use.

The unit was reportedly removed during the closure activities at the site and placed, along with any visual contamination, into the Capped Landfill Unit (SWMU 1). The former unit was located within the cutoff wall of the present Capped Landfill Unit (SWMU 1). At the time of the VSI, the area was covered with vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed condensate wastewater containing pentachlorophenol solution.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): An AWIC Inspection Report from February 4, 1976 suggested that concrete curbing be added around the separation units and at the ends of the treatment cylinders. The recommendation was based on the observation of ground surface covered with black oily liquids with no provision for containment. In addition, ground-water contamination has been confirmed beneath the former location of this unit.

RECOMMENDATIONS:

No Further Action	(*)

RFI Necessary	( )

REFERENCE(S): 1, 2, 59, 105, 133, 142

COMMENTS: * Continued efforts towards remediation of the Capped Landfill Unit (SWMU 1) and continued corrective action for contaminated ground water is suggested.

SWMU NUMBER: 10A-B

PHOTOGRAPH NUMBER: No longer present at facility

NAME: Collection Tanks

TYPE OF UNIT: Above-Ground Tanks

PERIOD OF OPERATION: Mid 1970's to 1981

PHYSICAL DESCRIPTION AND CONDITION: The unit has been described in association with the Creosote and Penta Recovery Systems (SWMUs 8 and 9). The facility SPCC plan, originally written around 1974 and updated in September 1981, mentions the collection tank (SWMU 10A) used for the accumulation of condensate drainage from the treatment cylinders prior to routing through the recovery systems. No physical description of the unit was given. Facility representatives suggest that the collection tank was part of the Creosote Recovery System (SWMU 8) but this does not agree with the SPCC plan.

A 1976 AWIC Inspection Report describes a collection tank (SWMU 10B) used for the accumulation of supernatant from the recovery systems, prior to discharge to the Vacuum Ponds (SWMU 12). The dimensions, construction and exact position of the tank are not mentioned.

The unit was presumably removed during the closure activities at the site and placed, along with any visual contamination, into the Capped Landfill Unit (SWMU 1). The first tank (SWMU 10A) was probably located near the treatment cylinders while the second tank (SWMU 10B) was probably located within the cutoff wall of the present Capped Landfill Unit (SWMU 1). At the time of the VSI, the area was covered with vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed condensate drainage from the treatment cylinders containing creosote oils and pentachlorophenol solution.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was noted in the available file material or observed during the VSI.

RECOMMENDATIONS:

No Further Action (*)
Confirmatory Sampling ( )
RFI Necessary ( )

REFERENCE(S): 105, 133, 143, 144

COMMENTS:

* Continued efforts towards remediation of the Capped Landfill Unit (SWMU 1) and continued corrective action for contaminated ground water is suggested.

SWMU NUMBER: 11 **PHOTOGRAPH NUMBER:** 1.5, 6.1

NAME: Barometric Condenser

TYPE OF UNIT: Condenser

PERIOD OF OPERATION: 1938 to November 1981

PHYSICAL DESCRIPTION AND CONDITION: The unit was located in the vicinity of the treatment cylinders in the central portion of the facility. The unit consisted of an elevated steel drum with a steel grate top and cone shaped bottom, and the concrete well to which it drained. The drum was approximately six feet in diameter, ten feet high, and was positioned on a 40 foot tower. A steam jet was attached to the side of the drum to pull the vapors from the treatment cylinders into the drum. Water was pumped to the top of the unit to create a water curtain for the condensation of vapors pulled from the treatment cylinders. From 1938 to 1966, the water was pumped from and returned to Threemile Creek (AOC D). In 1966 the Vacuum Ponds (SWMU 12) were installed for the supply and discharge of the condenser water. The condenser water drained to a hot well located beneath the condenser. The hot well was described by facility representatives as a concrete box measuring approximately five feet by five feet deep. The well was situated with the base approximately one foot into the ground. A shallow steel pipe drained the liquid from the well by gravity to the Vacuum Ponds (SWMU 12). The unit was reportedly operated 10 hours per day, 5 days per week, and 51 weeks per year.

The entire unit was reportedly removed during the closure activities at the site and placed within the Capped Landfill Unit (SWMU 1), along with any visual contamination. However, no soil sampling was performed to confirm that all contaminated soil was removed. At the time of the VSI, the former location of the unit was sparsely covered with vegetation. The former unit was located outside the containment wall of the Capped Landfill Unit (SWMU 1), but possibly within the security fence surrounding the landfill.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed pentachlorophenol and creosote vapors from the operation of the treatment cylinders. From 1966 to 1981, wastewater from the Vacuum Ponds (SWMU 12) was used to create the water curtain in the unit.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (U)
Ground Water (U) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was noted in the available file material or observed during the VSI. However, no integrity testing is reported to have been performed on the hot well thus leaving the possibility of release to soil unknown.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	( )
RFI Necessary	(*)

REFERENCE(S): 1, 79, 133, 141, 142, 144

COMMENTS: * An RFI of the entire treatment process area and the former locations of associated units has been suggested due to the amount of contamination in the area and unsubstantiated clean-up.

SWMU NUMBER: 12

PHOTOGRAPH NUMBER: The unit is located within SWUM 1; the ponds are pictured in the aerial photograph provided in Appendix D.

NAME: Vacuum Ponds

TYPE OF UNIT: RCRA-Regulated Surface Impoundment

PERIOD OF OPERATION: 1966 to November 1981

PHYSICAL DESCRIPTION AND CONDITION: The unit was located southwest of the treatment cylinders in the central area of the facility. It consisted of two parallel ponds, running north and south, each approximately 225 feet long, 25 feet wide at the top of the banks, 10 feet wide at the bottom, and 8 to 10 feet deep. The total capacity for both ponds together was approximately 420,000 gallons. The ponds were lined with gunnite, approximately four inches thick on the walls and eight inches thick on the bottom. Although the facility representative recalls the 15-feet wide area between the ponds being lined, file material indicates the area was unlined for some length of time. The two ponds were encircled by a three-feet high ring levee composed of clay core with a shell covered surface.

The ponds served as a source of contact cooling water for the Barometric Condenser (SWMU 11) and as an accumulation pond for process wastewater. The unit was RCRA-regulated due to the generation and storage of K001 sludge.

During closure activities around 1986, the sludge within the unit and sludges from some of the other units were solidified using lime kiln dust within the boundaries of the western pond. The sludge inventory was estimated to be approximately 3270 cubic yards in the Vacuum Ponds and the Aeration Pond (SWMU 16) combined.

The former unit is located within the cutoff wall of the present Capped Landfill Unit (SWMU 1). At the time of the VSI, the area was covered with vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed process wastewater from the treatment of lumber with creosote and pentachlorophenol, as well as K001 sludge generated from the wastewater.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): The unit reportedly was occasionally filled to the point of overflowing onto the unlined portion between the ponds. Ground-water contamination has been confirmed from the former unit in both the upper and lower aquifers. The ground-water contamination is currently being addressed under corrective action at the facility.

COMMENTS: * Continued efforts towards remediation of the Capped Landfill Unit (SWMU 1) and continued corrective action for contaminated ground water is suggested.

SWMU NUMBER: 13 **PHOTOGRAPH NUMBER:** The unit is located within SWUM 1

NAME: Flocculation Tank

TYPE OF UNIT: Above-Ground Tank

PERIOD OF OPERATION: Approximately 1971 to 1985

PHYSICAL DESCRIPTION AND CONDITION: The unit was located adjacent to the northwest corner of the Vacuum Ponds (SWMU 12), north of the Sand Filtration Beds (SWMU 14), and east of the Aeration Tank (SWMU 15), in the western half of the facility. The unit consisted of an above-ground steel tank with a capacity of approximately 7000 gallons. No secondary containment was associated with the unit.

Wastewater from the Vacuum Ponds (SWMU 12) was pumped to the unit for flocculation with Volclay and two polyelectrolytes. The clarified supernatant was then released to the Aeration Tank (SWMU 15) through above-ground piping. Collected sludge was shovelled weekly into the Sand Filtration Beds (SWMU 14) located on the northwest bank of the Vacuum Ponds (SWMU 12).

During closure of the site, the unit was reportedly cleaned out, cut into pieces and deposited within the landfill. The former location of the unit is within the cut-off wall of the Capped Landfill Unit (SWMU 1). At the time of the VSI, the landfill was covered with vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed process wastewater from the treatment of lumber with creosote and pentachlorophenol, as well as K001 sludge generated from the wastewater.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No secondary containment was associated with the unit for the containment of drippage or spills of sludge. Ground-water contamination has been confirmed beneath the former unit in both the upper and lower aquifers. The ground-water contamination is currently being addressed under corrective action at the facility.

RECOMMENDATIONS:

No Further Action (*)

COMMENTS:

* Continued efforts towards remediation of the Capped Landfill Unit (SWMU 1) and continued corrective action for contaminated ground water is suggested.

SWMU NUMBER: 14

PHOTOGRAPH NUMBER: The unit is located within SWUM 1

NAME: Sand Filtration Beds (2)

TYPE OF UNIT: RCRA-Regulated Sludge Treatment Unit

PERIOD OF OPERATION: Approximately 1971 to 1985

PHYSICAL DESCRIPTION AND CONDITION: The unit was located on the northwest bank of the Vacuum Ponds (SWMU 12), south of the Flocculation and Aeration Tanks (SWMUs 13 and 15), in the western half of the facility. The units were designed for the dewatering of the K001 wastewater treatment sludge.

The units consisted of open-topped concrete boxes, measuring 30 feet long, 15 feet wide and 3 feet deep. Each unit contained 1 to 2 feet of gravel and sand in the bottom, and had a maximum capacity of 50 cubic yards of sludge. The units were situated on top of the Vacuum Ponds (SWMU 12) levee such that the bottom of each box was above the level of the water in the ponds. Weep holes in the bottom of each box allowed the liquid to drain from the sludge into the Vacuum Ponds (SWMU 12).

Sludge from the Flocculation Tank (SWMU 13) was placed in the unit daily. One bed was used each week, allowing the sludge in the other bed to dry. Dried sludge was removed from the unit at the end of each week. The dried sludge was reportedly removed with a pitchfork into 55-gallon drums, which were then transferred to the Container Storage Area (SWMU 21) located within the warehouse at the facility.

The unit was located within the Capped Landfill Unit (SWMU 1). The unit was reportedly placed within the western Vacuum Pond (SWMU 12) with other SWMUs and waste during closure activities. At the time of the VSI, the landfill was covered with vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed K001 sludge from the treatment of wastewaters from wood preserving processes using creosote and pentachlorophenol.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No secondary containment was associated with the unit for the containment of drippage or spills of sludge. Ground-water contamination has been confirmed beneath the former unit in both the upper and lower aquifers. The ground-water contamination is currently being addressed under corrective action at the facility.

COMMENTS: * Continued efforts towards remediation of the Capped Landfill Unit (SWMU 1) and continued corrective action for contaminated ground water is suggested.

SWMU NUMBER: 15 **PHOTOGRAPH NUMBER:** The unit is located within SWUM 1

NAME: Aeration Tank

TYPE OF UNIT: Above-Ground Tank

PERIOD OF OPERATION: Approximately 1971 to 1985

PHYSICAL DESCRIPTION AND CONDITION: The unit was located directly west of the Flocculation Tank (SWMU 13), in the western half of the facility. It was reportedly an above-ground tank with a capacity of 20,000 gallons.

The unit received the supernatant from the Flocculation Tank (SWMU 13) after the sludge had been removed to the Sand Filtration Beds (SWMU 14). The supernatant was treated in the unit with ammonium nitrate (approximately one 25-pound bag per day). The treatment was performed on 20,000-gallon batches. The facility representative reported observing biological life in the tank, (e.g., plants, algae). According to the facility representative, no sludge accumulated nor was removed from the unit. Effluent from the unit was released to the Aeration Pond (SWMU 16) via above-ground piping.

The unit was reportedly cleaned out and dismantled during the closure activities of 1987. Pieces of the unit were buried in the Capped Landfill Unit (SWMU 1) along with the other dismantled tanks at the site. The former location of the unit is within the boundaries of the Capped Landfill Unit (SWMU 1). At the time of the VSI, the landfill was covered with vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit received supernatant from the flocculation of process wastewaters from wood treatment using creosote and pentachlorophenol.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was noted in the available file material or observed during the VSI. However, ground-water contamination has been confirmed beneath the area of the former unit.

RECOMMENDATIONS:

No Further Action (*)

COMMENTS: * Continued efforts towards remediation of the Capped Landfill Unit (SWMU 1) and continued corrective action for contaminated ground water is suggested.

SWMU NUMBER: 16 **PHOTOGRAPH NUMBER:** 1.3

NAME: Aeration Pond

TYPE OF UNIT: RCRA-Regulated Surface Impoundment

PERIOD OF OPERATION: Approximately 1973 to November 1981

PHYSICAL DESCRIPTION AND CONDITION: The unit was located along the western border of the facility, directly south of the Storage Tanks (SWMU 3). It consisted of an unlined surface impoundment whose base was at or below the water table. The unit measured approximately 375 feet long, by 85 feet wide, by 7 feet deep. The reported capacity was one million gallons, although the SPCC plan records it as approximately 550,000 gallons. The unit was surrounded by a dike constructed of a clay core with a shell surface.

The unit was constructed as part of the NPDES wastewater treatment system. It received effluent from the Aeration Tank (SWMU 15) and released its effluent to the Former NPDES Drainage Ditch (SWMU 17) through above-ground piping. The unit was reported to contain a 1.5 feet layer of sludge constituting approximately 1770 cubic yards of K001 hazardous waste. Sprinkler heads were installed in the pond to accelerate the aeration of the liquid. A fire house was located near the northeast corner of the unit with a pump from the pond for use in case of fire at the facility.

The unit was installed in an area of the facility which had been formerly used for the disposal of creosote wastewaters. The area is described in some files as an "inactive landfill", a "low-lying basin", or an "irrigation area". This area is described in more detail as the Creosote Wastewater Disposal Area (SWMU 18) in this report. The Treated Lumber Waste Pile (SWMU 19) is located directly south of the unit and may have been what was referred to as the "inactive landfill".

During closure of the unit in 1987, sludge and visually contaminated soil from the northernmost twenty percent of the unit was excavated and placed in the southern eighty percent to be solidified with lime kiln dust. Only the southern section was enclosed within the lime slurry cutoff wall of the Capped Landfill Unit (SWMU 1). No soil sampling was performed at the time of excavation to insure that all contaminated soil had been removed from the northern section of the unit. At the time of the VSI, the area was covered with vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed process wastewater from the treatment of lumber using creosote and pentachlorophenol, and the K001 sludge generated from that treatment.

RELEASE PATHWAYS:

Air	(L)	Surface Water	(L)	Soil	(U)
Ground Water	(U)	Subsurface Gas			(L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): Ground-water contamination in both the upper and lower aquifers has been documented from this unit. Well E-1, located in the area which was formerly in the northern section of the unit, contained 0.38 mg/l arsenic, 0.210 mg/l barium, 0.544 mg/l total volatile organics, and 0.244 mg/l total phenols. During the excavation of part of the unit for closure, no soil sampling was performed to determine if all contaminated soil had been removed. The boring logs of RW-1, E-1, and RW-2 from March and April 1991 describe creosote odor and wood chips in the soils from approximately 16 feet below surface level (bsl) to approximately 22 feet bsl.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	(*)
RFI Necessary	( )

REFERENCE(S): 1, 2, 3, 9, 27, 28, 29, 30, 31, 32, 33, 38, 39, 45, 49, 50, 51, 68, 78, 79, 87, 91, 93, 126, 133, 136, 137, 142, 143, 144

COMMENTS: * Soil sampling should be performed in the former location of the unit, outside of the lime slurry cutoff wall, at sufficient depths below the point of excavation to determine if all contaminated soil has indeed been removed.

SWMU NUMBER: 17 **PHOTOGRAPH NUMBER:** 17.1, 17.2, 17.3

NAME: Former NPDES Drainage Ditch

TYPE OF UNIT: Drainage Ditch

PERIOD OF OPERATION: 1938 to 1987

PHYSICAL DESCRIPTION AND CONDITION: The unit was located between the Vacuum Ponds (SWMU 12) and the Aeration Pond (SWMU 16), running from the northern portion of the facility south into Threemile Creek (AOC D). The unit received effluent from the Aeration Pond (SWMU 16), stormwater runoff from the facility, and in past operations, untreated process wastewaters. Discharge from the unit into Threemile Creek (AOC D) was regulated under NPDES Permit No. AL0001104 beginning in July 1974. Discharge from the unit was monitored for COD, total phenols, oil and grease, temperature and pH.

The unit measured approximately 800 feet long. At one time it reportedly measured 10 feet across from top bank to top bank, and was approximately four to five feet deep (plus two feet of sediment). As the unit flowed southward, the dimensions apparently spread to 20 feet across and approximately one foot deep. The unit drained approximately 40 acres of land, (the facility plus some land west of the site owned by Scott Paper). Flow from the plant was estimated at 12,000 gallons per day. Estimated annual runoff for the Alabama coastal region is approximately 30 inches of rainfall per year. The unit was reportedly influenced by tidal fluctuation due to its proximity to Threemile Creek (AOC D) and the Mobile River (the latter being approximately 2000 feet to the east).

The NPDES discharge point in the unit was approximately 700 feet above the confluence with Threemile Creek (AOC D). Approximately 400 feet south of this point a retention pond was constructed in the ditch for spill control. The retention pond was constructed prior to 1975 but the exact date is unknown. Baffled culverts were installed at the inlet and outlet of the retention pond. The culverts consisted of steel pipes, each measuring 7 feet in diameter and 20 feet long. The northern (inlet) culvert was equipped with a baffle across the invert to prevent silting with sand and other materials in the pond and to prevent the discharge of spilled creosote into the pond. Any creosote retained by the baffle would reportedly settle to the bottom of the ditch and periodically be pumped back to a tank to go through the Creosote Recovery System (SWMU 8).

The southern (outlet) culvert was also equipped with a baffle to retain spillage of pentachlorophenol solution by skimming the top of the retained runoff or spillage. The pond between the two culverts measured approximately 100 feet long, 30 feet wide, and 4.5 feet deep. The pond was designed to retain over 100,000 gallons of liquid. According to the facility representative at the VSI, the pond had not received any spillage during his tenure at the site (approximately 1975 to closure). From the second culvert to the end of the ditch (approximately 150 feet), the dimensions of the unit reportedly fluctuated in an irregular fashion.

During closure of the site, much of the contaminated sediment and soil from the unit was excavated, placed in the western Vacuum Pond (SWMU 12) and solidified with lime kiln dust. The Capped Landfill Unit (SWMU 1) covers approximately one third of the former unit. No soil sampling was performed beneath the excavated areas to confirm that all contaminated soil had been removed. At the time of the VSI, only the southernmost portion of the ditch remained at the site. The Current NPDES Drainage Ditch (SWMU 4) was created in the area west of the former ditch during the closure activities at the site. The current ditch enters the former unit approximately 30 feet from the confluence with Threemile Creek (AOC D).

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit received treated and untreated effluent from the treatment of lumber with creosote and pentachlorophenol, as well as untreated runoff from Treated Wood Storage Areas (AOC A) possibly containing pentachlorophenol and creosote drippage and stormwater runoff from the western side of the facility.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (U)
Ground Water (U) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): On November 13, 1984 during a RCRA 3012 Site Inspection, sediment samples from the unit were taken for analysis. A sample taken from the ditch at a point directly west of the northern end of the Vacuum Ponds (SWMU 12) was described as "a black, tarry emulsion starting at a depth of approximately 6 inches". The sample was found to contain 11.7 ppm fluorene, 4.2 ppm phenanthrene, 4.2 ppm anthracene, and 12.3 ppm fluoranthene. When portions of the unit were excavated for closure within the landfill, no soil sampling was performed to confirm that all contaminated soil had been removed.

RECOMMENDATIONS:	No Further Action ( ) Confirmatory Sampling (*) RFI Necessary ( )
REFERENCE(S):	1, 2, 15, 28, 29, 39, 49, 50, 51, 68, 87, 105, 126, 133, 136, 142, 143, 144
COMMENTS:	* Soil sampling should be performed in portions of the unit outside the Capped Landfill Unit (SWMU 1), at depths greater than the reported excavation and filling to confirm that all contaminated soil has been removed and disposed of properly.

SWMU NUMBER: 18 **PHOTOGRAPH NUMBER:** 4.2, 4.3, 18.1

NAME: Creosote Wastewater Disposal Area

TYPE OF UNIT: Marsh

PERIOD OF OPERATION: 1938 to 1973

PHYSICAL DESCRIPTION AND CONDITION: The unit consists of approximately six to seven acres of land located on the western border of the facility, south of the Storage Tanks (SWMU 3). The area has been described as a low-lying, shallow basin or marsh/wetlands. The Aeration Pond (SWMU 16) was constructed within the area in 1973, and the Treated Lumber Waste Pile (SWMU 19) is also located within the unit.

Reportedly from 1938 to 1966, wastewater from the creosote wood treating operations was discharged to this marshy area on the west side of the property. In 1966 the Vacuum Ponds (SWMU 12) were installed to recycle the process water used in the Barometric Condenser (SWMU 11). The Vacuum Ponds (SWMU 12) were designed as evaporation ponds, but more wastewater (approximately 3,000 to 5,000 gpd) was generated than could be evaporated in the ponds. This excess wastewater was sprayed over an area described as an "irrigational area" of the plant. Although the exact location of this area is unclear from the available file material, this "irrigational area" must be the marsh/wetlands on the western border of the property since the remaining areas of the facility were designated either for treatment or storage of raw materials and product.

In 1973 the Aeration Pond (SWMU 16) was constructed within this unit to receive treated effluent from the Flocculation and Aeration Tanks (SWMUs 13 and 15) which had been installed some time between 1971 and 1973. Throughout the operational period of this unit, effluent was reportedly released directly to Threemile Creek (AOC D).

The only areas within the unit addressed during the closure of the site were the Aeration Pond (SWMU 16) and the Spot Deposits (SWMUs 24A and 24B, two of the three identified) described in the quality assurance report of the closure. One of the Spot Deposits (SWMU 24A) was located directly southwest of the southwest corner of the Aeration Pond (SWMU 16), and the other (SWMU 25B) was approximately 100 feet directly south of the pond. The second unit reportedly appeared to be an old ditch. The two

Spot Deposits were reportedly scraped clean of visual contamination and backfilled with general fill. The excavated material was placed in the Capped Landfill Unit (SWMU 1). No sampling of the area below the excavations was reported.

During construction of the Capped Landfill Unit (SWMU 1), a considerable amount of fill material was placed in the area to help support the cutoff wall. Approximately 1.2 acres on the western border was leased from Scott Paper for access to the landfill and wells on the western side. At the time of the VSI, facility representatives were unfamiliar with former operations regarding the unit or the installation of the Aeration Pond (SWMU 16).

The Current NPDES Drainage Ditch (SWMU 4) runs through this former unit. Some areas of the ditch were noted to have dead vegetation, although it could not be determined whether the vegetation was stressed from contaminants or from standing water which may flood the area. Most of the area was thickly covered with tall vegetation making inspection difficult.

Facility representatives reported observing a leachate from the Scott Paper Company Solid Waste Landfill located across the property line from this unit in the past. The leachate reportedly entered the drainage ditch on Cavenham property. Cavenham facility representatives were not aware of the nature of the solid waste disposed in the Scott Paper landfill.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit received untreated wastewater from the treatment of lumber with creosote and possibly pentachlorophenol.

RELEASE PATHWAYS: Air (L) Surface Water (M) Soil (H)
Ground Water (H) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): On November 13, 1984 during a RCRA 3012 Site Inspection, sediment samples from the unit were taken for analysis. The inspection described creosote-type sludge and contaminated soils found in the area. Approximately six to eight inches of visible contamination/ discoloration was observed at a half-foot depth. Sediment samples taken contained 79.27 ppm naphthalene; 10.70 ppm 2-chloro-naphthalene; 24.0 ppm fluorene; 8.65 ppm phenanthrene;

8.65 ppm anthracene; 23.45 ppm fluoranthene; 24.47 ppm pyrene; and 71.1 ppm acenaphthene.

The boring log from April 18, 1991 of B-59A on the western border of the site describes large wood chunks and organic odor noted from approximately 14 feet below surface level (bsl) to approximately 44 feet bsl.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	( )
RFI Necessary	(*)

REFERENCE(S): 1, 2, 27, 28, 29, 39, 49, 51, 87, 126, 136, 142, 144

COMMENTS: * Cavenham should attempt to work with Scott Paper Company to determine: (1) the full extent of possible soil and groundwater contamination due to previous operations by Gulf Creosoting Company; and (2) if hazardous constituents are present in the leachate reported by facility representatives to be leaking onto Cavenham property from Scott Paper's solid waste landfill.

SWMU NUMBER: 19 **PHOTOGRAPH NUMBER:** 4.2

NAME: Treated Lumber Waste Pile

TYPE OF UNIT: Waste Pile

PERIOD OF OPERATION: Unknown to approximately 1987

PHYSICAL DESCRIPTION AND CONDITION: The unit was located south of the Aeration Pond (SWMU 16), along the western border of the facility, within the Creosote Wastewater Disposal Area (SWMU 18). The unit reportedly measured approximately 300 feet by 250 feet. The unit was described as an on-site landfill, containing treated and untreated pole cut-offs, poles and other miscellaneous debris. The pole cut-offs were generated in meeting specifications from customers regarding pole length, cap, and other product criteria.

During closure of the site, the poles and debris were removed to the Capped Landfill Unit (SWMU 1). Beneath the unit a black organic sludge was observed. The sludge was tested for creosote contamination and found to be "relatively" clean according to the facility and the contractor conducting the quality assurance. Sampling data was not available and no clean-up of the sludge is mentioned.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed untreated lumber and lumber treated with creosote and pentachlorophenol, along with general wood debris.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (M)
Ground Water (M) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): A black organic sludge was observed when the waste pile was removed to the landfill. The facility reportedly did not remove the sludge nor contain the untreated surface runoff from the area.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	( )
RFI Necessary	(*)

REFERENCE(S): 1, 2, 27, 51, 87, 133

COMMENTS: * The RFI should be performed in conjunction with the investigation of the entire Creosote Wastewater Disposal Area (SWMU 18) within which the unit was located.

SWMU NUMBER: 20 **PHOTOGRAPH NUMBER:** Units no longer present at facility

NAME: Satellite Accumulation Areas (SAAs)

TYPE OF UNIT: SAAs

PERIOD OF OPERATION: Approximately 1938 to 1987

PHYSICAL DESCRIPTION AND CONDITION: The unit consisted of 55-gallon steel drums located in waste treatment areas of the facility and at the entrances to the bath houses. The drums were constructed of low carbon steel and were compatible with K001 wastes. In addition, the drums met U.S. Department of Transportation Specification No. 17C. The facility representatives could not give an exact number of SAAs, but it is estimated to be approximately seven.

The units received used contaminated articles such as gloves, coveralls, etc., on an as needed basis. Tops were reportedly kept on the containers at all times except when adding wastes. Once full, the container was transferred to the Container Storage Area (SWMU 21) for storage prior to final disposal at a licensed landfill.

All drums/containers containing hazardous materials were removed offsite during closure of the plant. The units are no longer in use at the facility.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The units received used articles such as gloves or coveralls contaminated with creosote oils or pentachlorophenol solution.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was noted in the available file material or observed during the VSI.

COMMENTS:	None	

SWMU NUMBER: 21

PHOTOGRAPH NUMBER: The unit is located within SWUM 1

NAME: Container Storage Area

TYPE OF UNIT: RCRA Storage Area

PERIOD OF OPERATION: Approximately 1971 to 1985

PHYSICAL DESCRIPTION AND CONDITION: The unit was located in the southern portion of the facility warehouse, directly east of the Aeration Pond (SWMU 16). The unit was RCRA-regulated because it stored hazardous wastes for greater than 90 days.

The facility warehouse was described as a wood-framed building with tin-sheet walls and roof, although prior to 1975 the building was predominantly constructed of wood. In addition to hazardous waste, the warehouse was used for storage of miscellaneous tools, steel bonding materials, spare parts, and railroad servicing equipment. The container storage area covered approximately 700 square feet and was situated on a wooden floor, approximately two feet off the ground. No secondary containment was associated with the unit. Steel 55-gallon drums containing dried K001 sludge were stored in the unit prior to offsite disposal. The drums were constructed of low-carbon steel and were compatible with K001 wastes. In addition, the drums met U.S. Department of Transportation Specification No. 17C. The wastes were primarily generated from the Sand Filtration Beds (SWMU 14) and from the cleaning of treatment equipment or tanks.

Crown Zellerbach records indicate that wastes were sent to Dubose Oil Recycling Facility in Pensacola, Florida, and to Chemical Waste Management in Emelle, Alabama. At the time of closure, all remaining drums were reportedly transferred offsite for disposal and the warehouse building was dismantled and buried in the Capped Landfill Unit (SWMU 1). The location of the former unit is within the cutoff wall of the closed landfill. At the time of the VSI, the landfill was covered with thick vegetation.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed drums of dried K001 sludge, and drums of articles contaminated with creosote oils or pentachlorophenol solution.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was noted in the available file material or observed during the VSI.

SWMU NUMBER: 22 **PHOTOGRAPH NUMBER:** 22.1, 22.2

NAME: North Tar Deposit

TYPE OF UNIT: Waste Pile

PERIOD OF OPERATION: Unknown to Approximately 1987

PHYSICAL DESCRIPTION AND CONDITION: The unit was located in the northernmost portion of the facility, north-northeast of the treatment area and north of the Former Conical Burner (SWMU 25). The unit has been described as two piles split by one of the railroad tracks into the site. The overall dimensions of the unit were estimated at 100 feet by 30 feet by five feet high.

The unit reportedly received the wash out from the treatment cylinders. The treatment cylinders were washed out periodically to remove the sludge which collected in the bottom of the cylinders. The liquid/sludge was drained from the treatment cylinder into a large steel, bowl-shaped door from a former treatment cylinder. The door was suspended by cable from the crane used to transport the lumber in the yards. The liquid was drained off into the recovery systems/wastewater treatment, and the solids/sludge was transported to the uncontained waste pile for disposal. The facility representative could not recall how often this procedure occurred. Surface drainage from the unit entered the Earthen Drainage Ditch (AOC G) which flow unmonitored into Threemile Creek (AOC D).

During closure activities, the surface deposits were removed and placed in the western Vacuum Pond (SWMU 12) within the Capped Landfill Unit (SWMU 1). Soil in the area was reportedly excavated until the site appeared visually clean. The total volume of material excavated was estimated at 1122 cubic yards. The excavated material was replaced with uncontaminated general fill material. No soil sampling was performed to determine if all contaminated soil had been removed from the site.

At the time of the VSI, the area was partially overgrown with vegetation. Low-lying areas of the access road appeared to either be stained or wet from the water table below.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit received sludge from the treatment cylinders containing creosote oils and possibly pentachlorophenol solution.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (U)
Ground Water (U) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): Soil sampling was not performed at the time of excavation to determine if all contaminated soil had been removed. In addition, no secondary containment was associated with the unit to prevent release to the ground water.

RECOMMENDATIONS:
No Further Action ( )
Confirmatory Sampling (*)
RFI Necessary ( )

REFERENCE(S): 1, 2, 27, 28, 87

COMMENTS: * Soil sampling should be performed at sufficient depths below the point of excavation and around the perimeter of the excavation to determine if all of the contaminated soil has been removed.

SWMU NUMBER: 23 **PHOTOGRAPH NUMBER:** 17.1, 23.1, 23.2

NAME: Creek Tar Deposit

TYPE OF UNIT: Waste Pile

PERIOD OF OPERATION: Unknown to Approximately 1987

PHYSICAL DESCRIPTION AND CONDITION: The unit was located on the bank of Threemile Creek (AOC D) at the southern end of the railroad tracks from the treatment cylinders. A shell-covered access road bordered the unit to the north. The pile was bordered on lower elevations to the east and south by decaying treated log bulkheads. The unit was reportedly being eroded by the creek on the southeast corner.

Facility representatives have speculated that this waste pile was generated in the same manner as the North Tar Deposit (SWMU 22), i.e., through accumulating washout sludge from the treatment cylinders. The material in the waste pile reportedly appeared to have been dumped from a railroad car. The unit covered approximately 50 feet by 80 feet, and contained material approximately 5 feet thick. The surface was described as hard-baked and highly fractured. General surface elevation sloped from approximately 4.5 feet msl at the northern end to 3 feet msl at the southern end, allowing some runoff to discharge directly to Threemile Creek (AOC D).

During closure of the site, material and soil were excavated to a depth of six feet. Excavated material was disposed in the solidified Vacuum Ponds (SWMU 12) and replaced with general sand backfill. The excavation found tar deposits, old poles and piles. The excavation was continued until the material removed looked visually clean. No soil sampling was performed to determine if all contaminated soil had been removed from the site.

At the time of the VSI, the area of the former unit was partially covered with vegetation. A waste pile of concrete, asphalt and old railroad ties was observed in the vicinity of the former unit.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit reportedly managed sludge from the treatment cylinders containing creosote oils and pentachlorophenol, along with old poles and railroad ties.

RELEASE PATHWAYS:

Air	(L)	Surface Water	(L)	Soil	(U)
Ground Water	(U)	Subsurface Gas			(L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): A RFA was performed on the unit in October 1986 by Ebasco Services Incorporated under a contract with EPA. The RFA included a sampling report and recommended a remedial investigation of the unit. Direct evidence of sediment, soil and surface water contamination was visually observed. Sediment and soil contamination was confirmed with sampling. K001 contaminants were found in soils ranging from 1.8 to 819 mg/kg, and in sediments around the waste pile ranging from 36 to 70 mg/kg. Although leachate directly entering the creek was observed, surface water sampling only showed traces of pentachlorophenol and fluoranthene. It was concluded that the large tidal volume in the creek was diluting the leachate flow to below detection limits. The unit was excavated during the closure of the site in 1987; however, sampling was not performed to confirm that all contaminated soil had been removed.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	(*)
RFI Necessary	( )

REFERENCE(S): 1, 2, 27, 28, 35, 51, 87

COMMENTS: * Soil sampling should be performed at sufficient depths below the point of excavation and around the perimeter of the excavation to insure that all contaminated soil has been removed.

SWMU NUMBER: 24A-C **PHOTOGRAPH NUMBER:** 1.5, 6.1

NAME: Spot Deposits

TYPE OF UNIT: Waste Piles

PERIOD OF OPERATION: Approximately 1938 to 1987

PHYSICAL DESCRIPTION AND CONDITION: The unit consists of three areas designated for cleanup during the closure activities at the facility. Two of the areas (SWMUs 24A and 24B) have been discussed previously in the Creosote Wastewater Disposal Area (SWMU 18). SWMU 24A was located directly southwest of the southwest corner of the Aeration Pond (SWMU 16), and SWMU 24B was approximately 100 feet directly south of the pond. The Southern Deposit (SWMU 24B) reportedly appeared to be an old ditch, possibly part of the Current NPDES Drainage Ditch (SWMU 4). SWMU 24C was located directly east of the treatment cylinders and may have consisted of three spots. This unit measured approximately 15 feet by 10 feet total, with an estimated depth of 2 feet. SWMUs 24A and 24B were not given dimensions in the available file material and facility representatives were not familiar with the sites.

SWMUs 24A and 24B within the Creosote Wastewater Disposal Area (SWMU 18) were reportedly scraped clean to visual standards and backfilled with general fill during closure of the site. The excavated material was placed in the Capped Landfill Unit (SWMU 1). No sampling of the area below the excavation was reported. SWMU 24C, adjacent to the treatment cylinders, was excavated to a depth of two feet. The total estimated volume of SWMU 24C was twelve cubic yards. The material excavated from this area was also deposited in the Vacuum Ponds (SWMU 12) within the landfill.

At the time of the VSI, these areas were covered with vegetation and were difficult to locate due to the extreme change in the facility's appearance over the past five years. Only SWMU 24A is located within the boundaries of the Capped Landfill Unit (SWMU 1).

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit appeared to have managed dried K001 sludge and treatment cylinder washout containing creosote oils and pentachlorophenol solution.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (U)
Ground Water (U) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): On November 13, 1984 during a RCRA 3012 Site Inspection, sediment samples from the unit within the Creosote Wastewater Disposal Area (SWMU 18) were taken for analysis. The inspection described creosote type sludge and contaminated soils found in the area. Approximately six to eight inches of visible contamination/discoloration was observed at a half-foot depth. Sediment samples taken showed 79.27 ppm naphthalene; 10.70 ppm 2-chloro-naphthalene; 24.0 ppm fluorene; 8.65 ppm phenanthrene; 8.65 ppm anthracene; 23.45 ppm fluoranthene; 24.47 ppm pyrene; and 71.1 ppm acenaphthene.

RECOMMENDATIONS:

No Further Action	( )
Confirmatory Sampling	( )
RFI Necessary	(*)

REFERENCE(S): 1, 2, 27, 28, 87

COMMENTS: * The sampling of SWMU 24B should be performed in conjunction with the investigation of the entire Creosote Wastewater Disposal Area (SWMU 18). The investigation of SWMU 24C should be incorporated into the RFI of the treatment process area.

SWMU NUMBER: 25 **PHOTOGRAPH NUMBER:** No longer present at the facility

NAME: Former Conical Burner

TYPE OF UNIT: Incinerator

PERIOD OF OPERATION: June 1969 to October 1973

PHYSICAL DESCRIPTION AND CONDITION: The unit was located on the eastern border of the facility, within the raw material/untreated lumber storage, east of the former pole deck and debarking operations. The unit was a single-chamber incinerator used for the burning of facility refuse, pine bark, and shavings. The pine bark and shavings were generated through debarking and pole maching operations (making the poles round).

The unit was described in the air permit application as a 45-feet diameter conical teepee burner; other references refer to it as the bark burner. The stack on the unit reached a height of 45 feet and had an inside diameter of 18 feet. The unit was rated with a capacity to burn 5000 pounds of material per hour. The unit was fed directly from the pole machine and debarking operations and was in operation 8 hours per day, 5 days per week, 52 weeks per year. The unit was to be shut down by June 1973, once the facility ceased the debarking operations or found a new method of disposal of the wastes generated.

The facility was issued a conditional permit to operate #503-2004-0001 for the unit on December 8, 1972. The permit was to expire in December 1973. However, the facility reportedly ceased operations of the unit in October 1973.

At the time of the VSI, the location of the former unit was covered with vegetation. The unit was reportedly removed from the property long before closure activities commenced.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed facility refuse, pine bark, and shavings from pole maching and debarking operations.

RELEASE PATHWAYS: Air (L) Surface Water (L) Soil (L)
Ground Water (L) Subsurface Gas (L)

HISTORY AND/OR EVIDENCE OF RELEASE(S): No evidence of release was noted in the available file material or observed during the VSI.

	Confirmatory Sampling	( )
	RFI Necessary	( )

REFERENCE(S): 1, 138, 140, 141

COMMENTS: None

SWMU NUMBER: 26 **PHOTOGRAPH NUMBER:** No longer present at the facility

NAME: BFI Dumpster

TYPE OF UNIT: Dumpster

PERIOD OF OPERATION: Possibly 1973 to Present

PHYSICAL DESCRIPTION AND CONDITION: The unit consists of a refuse dumpster managed by Browning Ferris Industries (BFI). During the active life of the facility, the unit was located next to the northeast corner of the Aeration Pond (SWMU 16). At that time refuse was picked up weekly by BFI. Since closure, BFI has been on call for refuse pick-up from the site. No dumpster was observed on site during the VSI. Facility representatives said another dumpster will be kept at the site once the ground-water treatment operations commence, probably in March 1992.

WASTES AND/OR HAZARDOUS CONSTITUENTS MANAGED: The unit managed general facility/office refuse.
